Infants begin the lifelong task of developing the skills of regulating emotions in terms of inhibiting and/or minimizing the intensity and duration of their emotional experiences. Although caregivers are important emotion regulators throughout infancy and childhood, infants also engage in a variety of self-soothing behaviors from an early age, including thumb sucking, gaze aversion, and distraction. Furthermore, as young children develop in their self-awareness and ability to use language to describe feeling states, they are also able to verbalize contexts that make them feel distressed or give them joy (Kopp and Neufeld, 2002).

Emotion Understanding

Infants' basic abilities in distinguishing between positive and negative emotions occur within the first few months of life. We do not know yet whether distinguishing between these emotions is accompanied by an understanding of the feeling state of the other person, although social referencing studies, in which 12–14 month olds pause in response to caregivers' fear responses, indicate infants' use of emotional information to inform how they should react to novel situations and potential danger, in particular. Although infants may begin to use social referencing as early as 6 months of age, they become increasingly skilled at checking in with caregivers before acting to see if their faces reflect fear, happiness, or anger. Young children may also utilize social referencing when interested in feedback, such as when looking for validation from a caregiver after completing a difficult task or checking for anger when reaching for a forbidden object. Although some 2 year olds are able to identify and also generate facial expressions reflecting basic emotions upon demand, these skills become increasingly developed over time.

Related Domains

Related research domains that inform our understanding of emotional development in infancy and early childhood are those of temperament and attachment. Temperament literature describes infants' behavioral styles in terms of their general emotional responses to a variety of situations. Researchers have proposed several ways of classifying infants' temperament, and these include components of positive and negative affectivity, self- or emotion regulation, and activity level. Many infants' overall behavior is characterized by a general display of positive affect and ability and a propensity to adapt easily to novel situations, including emotional adaptability. However, other infants' overall demeanor may reflect general negative affect, and they may show little ability to attenuate negative emotion expressions, even after no longer being in the presence of the cause of distress. Temperament classifications tend to demonstrate stability throughout childhood, even when children's environmental niches shift. Temperament is likely genetically inherited, however, increasing evidence supports the substantial role of environmental experience in modifying outcomes (Henderson and Wachs, 2007).

Attachment describes the emotional bond between the infant and the caregiver. Theories of attachment often note the importance of the caregiver's responsiveness to the infant's emotional expression as a pathway by which a deep, trusting emotional bond is created. Infant–caregiver attachments develop from infants' instinctive preference toward other humans at birth to attachment formation with primary caregivers as infants distinguish between familiar others and strangers (Van Ijzendoorn and Sagi-Schwartz, 2008). The discussion of attachment is relevant because it reflects how emotional development occurs in the context of social relationships and the importance of emotional bonds for the developing child.

Although it may be tempting to accept the developmental trends of emotion competence previously described as universal, culture may impact the emergence of emotion and emotion-related components. Many of the laboratory and naturalistic observation paradigms used to measure and explore infants' emotional functioning were developed to examine emotional competence based on Western theory with Western samples. However, when similar yet culturally appropriate paradigms have been used to explore infants' emotional functioning, some universal assumptions have been challenged. For example, when a culturally appropriate version

of the commonly used strange situation paradigm was used with Nso 1 year olds, the 'universal' representation of secure attachment as characterized by stranger-evoked distress and caregiver-evoked comfort was not present. In contrast, a large number of Nso infants showed no emotional reaction to the stranger (Keller and Otto, 2009). These results suggest that we need to re-think both the operationalization and measurement of attachment in terms of cultural norms and expectations. We further discuss the consideration of culture in emotional development in infancy and how parental socialization inculcates cultural expectations for infants' emotional functioning.

Culture

Culture, as we define it, is the shared pattern of beliefs, values, behaviors, and language learned through inter- and intragenerational socialization. Culture determines the physical and social environments of infant development (Super and Harkness, 1986). To understand how culture impacts emotional development, researchers have targeted emotion socialization as the mediating pathway between cultural context and children's emotional competence and functioning. Parent–child relations are infused with culture through practices that dictate the way that parents and children interact with each other and the cultural belief systems that impact the interpretation of those interactions. Infants also learn about culture through experience-expectant (species-typical neural preparedness to integrate information from the environment) and experience-dependent (individual neural changes due to learning and experience) processes (Keller, 2007). Throughout infancy, children develop emotional competence by increasingly integrating information from parent–child interactions across cognitive, physiological, and motoric domains. We briefly review the cross-cultural literature on parental emotion socialization before discussing the nature of culture-specific features and cultural commonalities of emotion development in early childhood.

Emotion Socialization: A Cultural Pathway to Emotional Development

Parental emotion socialization is thought to be one of the most important influences on infants' and children's emotional development; caregivers' own emotional experience, communication, sensitive responsiveness, and understanding of their infants' needs help to shape the emotional world of early childhood. Parental socialization is also one of the primary ways in which culture is imparted in that caregivers' emotional socialization behaviors are themselves shaped/governed by the expectations, beliefs, and shared knowledge of the cultures in which they live. Cross-cultural studies have noted a variety of cultural differences in parent beliefs and expectations about children's emotions, early caregiver–child interactions, and parent emotion socialization, all of which have implications for early childhood emotion development.

Several cultural frameworks have been identified to organize cultural effects on parenting practices and beliefs. These include independence–interdependence, power distance, children's place in family and culture, ways children learn, and value of emotional experience and expression (Halberstadt and Lozada, 2011). The most common of these cultural frameworks is that of *independence–interdependence*, which is also often referred to as *individualism–collectivism*. Western cultures (i.e., United States, Germany, Greece) are most often associated with being independent or individualist. These societies consider children as separate entities from the caregiver and encourage the development of autonomy. Individualistic emotional competence encompasses self-awareness, and emotional expression and regulation of socially disengaged emotions (e.g., happiness, anger, and frustration) as assertions of individuality and autonomy. Eastern cultures (i.e., Japan, China, India) are most often described as interdependent or collectivist. Interdependent societies consider children as part of their social groups (e.g., family) rather than as individuals and encourage emotional bonding and unity between the caregiver and the child. These societies also encourage interconnectedness and group harmony. Interdependent emotional competence encourages an understanding of emotion in relation to what others are feeling, and socially engaged emotions (e.g., empathy, shame, guilt). A central goal in regulating emotional expression is to keep family and group harmony intact (Friedlmeier et al., 2011). Although researchers agree that one culture may tend toward a more individualist or collectivist orientation, it is also understood that these two orientations can exist simultaneously within cultures, with orientations existing along continuums rather than a dichotomy of polar opposites.

Parenting practices that promote infants' and children's emotional competence, as defined by the various frameworks supported in the culture, are reflected in differences in maternal–infant body contact, feeding patterns, responses to infant vocalizations (both distress and nondistress related), sleeping patterns, and even in other aspects of the child-rearing environment such as the presence of toys or the number of caregivers and family members that the infant comes in contact with on a daily basis. For example, the presence of many toys in the infants' environment is characteristic of independent cultures and can be used to elicit positive emotion in infants or to distract from and regulate negative emotion expression. However, infants in interdependent cultures may not have as much need or opportunity to play with toys when family members or others serve as the primary elicitors and regulators of emotion. These cultural differences may affect the frequency of emotional experience or expression, and skill in understanding the emotions of self and others, but they also do much to transform the action possibilities in the environment (called affordances in the perceptual theory developed by James and Eleanor Gibson), in which the entire emotional landscape of infants and children are embedded. To continue this example: action possibilities afforded by toys are very different from those afforded by people. Materialism may also serve as an independent influence on children's emotional development; as some interdependent cultures become more consumer-oriented, or as some families within interdependent cultures shift to a greater toy-focused parenting strategy, children's orientation of emotional satisfaction derived from interpersonal relationships may shift to that of object engagement.

Empirical studies have observed many differences in parental socialization across independence–interdependence orientations, as well as the other frameworks noted earlier. In a series of studies that compare maternal expectations of infants and mother–child interactions between urban middle class German mothers (an independent cultural context that also includes a framework which values children's emotional experience and expression) and rural farming Cameroonian Nso mothers (an interdependent context that also includes a framework which values children's low emotional expressivity), German mothers expected to see emotional expression early in infancy and reported having low expectations of children's emotional control when 3 years old. Behaviorally, they engaged in more face-to-face contact, positive vocalizations, smiling, and contingent responding in early infancy. In contrast, Nso mothers had higher expectations for emotional control, even in infancy. Behaviorally, they engaged in less face-to-face contact and smiling so as to avoid arousing infant emotion. All of these reflect Nso expectations that good children are calm with little emotional expressiveness, except in the case of socially engaged emotions such as shame and guilt (Keller and Otto, 2009). As such, the German and Nso cultures varied not only on the independent–interdependent orientation, but also in their beliefs about the value of emotional experience and expression, and about how and when children learn about and control their emotions.

Perhaps the most striking evidence for the early impact of cultural beliefs and norms on infants' emotional development is the shift in smiling during mutual gaze between 6 and 12 weeks of age by the Nso and German infants; this age was studied so as to capture any developments in emotional development at what is thought to be the 2-month shift in infants' systemic reorganization. Consistent with their beliefs and values regarding emotion expression, German mothers smiled at their infants more so than Nso mothers; although infant behavior is not different cross-culturally at 6 weeks, it is markedly different by 12 weeks, at which point German infants have substantially increased their smiling duration and imitation of mothers' smiles, more closely matching their mothers' behavior. Nso infants' smiling stayed fairly stable at its lower level, again reflecting the values of Nso society for less expressiveness (Wörmann et al., 2012). It is likely that cultural norms and nuances impact infants' and children's organization and re-organization of their understanding of the social world around them, and their responses to that world.

As noted above, although the framework of independence–interdependence is a powerful tool to use in understanding cross-cultural differences, other frameworks are needed to fully understand the richness of cross-cultural differences, as many cultural differences in emotion socialization have been noted in societies that both reflect interdependent cultural contexts. For example, the rural villages of the Tamang and Chhetri-Brahmin people in Nepal are similar on many characteristics of subsistence living and belief systems of social conformity and group harmony. However, the Tamang practice Tibetan Buddhism and beliefs of egalitarianism, tolerance, and the value of mild, socially engaged emotions. The Chhetri-Brahmin are high caste Hindus whose hierarchical place in society reflect spiritual purity and who value self-control. Their high-society status, even in rural villages, promotes feelings of pride and social dominance. The different belief systems due to religious affiliations represent the cultural framework of the value of emotional experience and expression and is manifest in differing patterns of socialization; Chhetri-Brahmin mothers responded more positively to their young children's anger yet ignore children's expressions of shame. However, Tamang mothers responded with rebuking their children's anger (Cole et al., 2006).

Although cross-cultural emotion socialization studies yield examples of many differences in parenting practices impacted by cultural beliefs and orientations, we also note evidence of universal trends in emotion socialization across cultures. For example, although maternal sensitivity may vary in its behavioral manifestations (e.g., visual or vocal contingency versus proximal contingency, frequency versus intensity of smiling in face-to-face interactions), its positive influence on infant emotional functioning is apparent across cultures. Similarly, differential responding to powerful (e.g., anger) and powerless (e.g., sadness) emotions may serve varying functions for the development of autonomy and relatedness, and also for one's place in terms of the power distance framework, yet socialization practices that dismiss or punish children's emotions are related to later internalizing and externalizing in later childhood in several cultures (Friedlmeier et al., 2011). The desire for culturally appropriate emotional competence in infancy is evident across cultures, but can cultural differences in emotion experience, expression, and understanding be observed in infancy and early childhood? Several findings from cross-cultural infant and preschool research are reviewed and discussed in the context of cultural orientations.

Cross-Cultural Findings of Emotional Competence in Infant and Early Childhood

Emotion Experience and Expression

Infant emotion and experience appear indistinguishable at birth, yet as young children develop in their ability to understand the self and others' expectations, the two abilities become differentiated. Cross-cultural differences in these abilities likely reflect cultural variations in beliefs about the value of emotional experience and expression and beliefs in the way children learn about emotions. For instance, comparisons of European American, Chinese, and Japanese infants suggest that Chinese infants are less expressive overall than both European American and Japanese infants; however, there were no significant differences in the frequency of genuine smiles and in the latency and frequency of crying (Camras et al., 1998). Differences between European American and Chinese infant emotion expression is expected because of cultural differences in the value of emotion, however, differences in Chinese and Japanese infant expression is surprising given that the cultures appear to be similar not only in collectivist orientation but also in having to place high value on the restraint of emotion expression.

Although some young children of different cultural contexts exhibit different emotional reactions to comparable experiences, others show differences in the maintenance or regulation of that emotion over time. For instance, Japanese and German preschool girls were exposed to self- and other-focused distress

conditions to examine whether they would display culture-specific emotional reactions to their own experiences of frustration or the frustration of a playmate. Children in both groups displayed similar spontaneous distress reactions to both conditions, but the trajectories of their reactions varied by self-focused distress and other-focused distress conditions. Specifically, German girls sustained their distress throughout the duration of the self-focused distress condition but decreased their expressions in the other-focused condition. Japanese girls showed distress maintenance in the other-focused distress condition but decreased affect in the self-focused distress condition. These findings demonstrate that although young children may display similar emotional reactions and emotion regulation patterns, culture-specific display rules may dictate the context in which these emotional experiences occur (Trommsdorff and Friedlmeier, 2010). Culture-specific display rules may also be evident in young children's emotion-regulation behaviors. For instance, although both Japanese and German preschool girls engaged in support-seeking behaviors when distressed, Japanese girls did so by seeking closer proximity to their mothers whereas German girls engaged in social referencing their mothers by eye contact (Friedlmeier and Trommsdorff, 1999). Differences in the focus of group harmony versus autonomy in Japanese and German culture contribute to differences in the social context of these children's reactions and the methods by which they seek to regulate emotion.

Although the above, and many other studies of emotion development, identify experiential and expressive differences across cultures, other studies highlight universal aspects of emotion expression development. Studies that compare the muscular configuration of emotion expression find that infants across culture show similar expressions for happiness, sadness, and anger. Although the differences in the support for and participation in the social smile of German and Nso infants change dramatically in the first 12 weeks of life, as discussed earlier, it must be noted that the intensity of smiling between mothers and infants did not differ across the two groups (Wörmann et al., 2012). When taken together with the previous work on Japanese and German preschoolers, this work suggests that culture may have more of an impact on the context, frequency, duration, and meaning of emotional experiences, but perhaps not on the basic expression of the emotion (e.g., intensity and muscular configuration).

Emotion Understanding

Children's emotion recognition abilities are considered valuable across cultures but perhaps for different reasons. For example, in interdependent cultures that promote the expression of socially engaged emotions, a child must be able to know what the other person is feeling in order to show sympathy. In independent cultures, a child may need to know what another person is feeling in order to respond in a way that would allow for the other person to have privacy as they worked to regulate their emotional experience. Although few cross-cultural studies have examined emotion recognition in early childhood, there is evidence to suggest early cross-cultural differences in emotion recognition. For instance, Chinese 4 year olds were significantly more accurate at emotion recognition than Australian 4 year olds (Markham and Wang, 1996). This is somewhat surprising given that the expectation is that children in independent cultures (e.g., Australia) would have more opportunities to learn about emotion expression because emotion expression is valued. However, it may be that children in an interdependent culture like China may gain more experience with being able to read affective information from microexpressions of emotion, making them more sensitive to the facial cues in the emotion recognition task.

Similar to the dearth of cross-cultural research on emotion recognition in early childhood, very few studies have examined emotion understanding in infancy and early childhood. However, some insight into early emotion knowledge can be gleaned from studies in which children report their feelings in response to hypothetical scenarios, and these studies suggest culture-specific patterns. In response to vignettes about emotion-eliciting situations, Nepali Tamang and Chhetri-Brahmin children as young as 6 years old reported emotions consistent with the display rules of their culture. Specifically, Tamang children were more likely to report that they would feel 'just okay' than Chhetri-Brahmin children who were more likely to report feeling anger to potentially anger-eliciting situations. This pattern reflects the Tamang adherence to Buddhist principles of avoiding strong emotionality. Although the Chhetri-Brahmin children were more likely to report that they would feel anger than Tamang children in response to the same vignettes, they were also more likely to report masking in those situations, consistent with their Hindu-oriented beliefs to engage in self-control (Cole and Tamang, 1998). The cultural differences among these two peoples support the importance of knowing a culture's framework with regard to the value of emotion experience and expression.

Future Directions

Cross-cultural research on emotion in infancy and childhood has yielded a great deal of knowledge on both the cultural commonalities and differences in the development of children's emotion experience, expression, and understanding. However, our knowledge of how these developmental trajectories vary is still limited to relatively few cultures which mainly vary on independent–interdependent conceptions of the self. Empirical studies that examine emotional competence across cultures that vary in their views of structural hierarchy, views on children's societal roles and competence, and beliefs about emotion may yield a more nuanced view in how cultural belief systems impact parental emotion socialization and changes in emotional competence in early childhood (Halberstadt and Lozada, 2011). Above all, advancements in culturally appropriate theories and methods are needed to make more consistent observations of the precursors of emotional development in a variety of cultures. Such advancements would allow emotion researchers to answer many of the basic questions about the nature of emotion that are still debated today.

Early Life Influences on Health and Mortality in Adulthood

Ken R Smith and Heidi A Hanson, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, USA

Abstract

Conditions present early in a person's life are potentially important for explaining adult mortality risks. Many questions remain about which early life conditions contribute to these health and longevity differentials. In this article, we examine several key early life conditions that connect prenatal and early childhood factors to adult mortality risks with special attention given to the events proximate to the individual's birth and during childhood. Challenges and themes for future research that arise from this work are also presented.

Introduction

Humans have a distinctive and nearly universal pattern of mortality: elevated rates among newborns and infants that are followed by a decline through adolescence and young adulthood and then a subsequent and steady increase into old age, with the possibility of late-life mortality deceleration. The general shape of this mortality schedule is commonplace though the absolute levels vary across populations and historical periods. But what is of greatest interest for the present discussion is the connection between the left and right segments of this mortality profile. Factors affecting infant health and survival are manifold but are extremely sensitive to characteristics and correlates of fertility of the parents and the offspring's early years of dependency and childhood. These early characteristics represent important factors and pathways that serve to alter the mortality risks of newborns, infants, and young children. But more importantly for our purposes, these same traits may impart a lasting imprint on their *surviving* children when these offspring reach adulthood and well into their senior years. This article, therefore, examines the connection between prenatal and early childhood characteristics and later onset mortality risks with exclusive attention given to the events proximate to the individual's birth and during childhood.

Our conceptual lens is decidedly biodemographic, a perspective that embraces social, biological, and genetic perspectives. The literature on the biodemography as well as the epidemiology of the late effects of early life conditions is vast with many important mechanisms and debates represented – more than can be comprehensively synthesized in one chapter – but we take the position that these earliest of circumstances, those comprising gestation through infancy and childhood, are arguably among the most fundamental features of an individual's life history. Moreover, these early moments are also crucial for setting the stage for other putative early circumstances that are the focus of much research in the field (Elo and Preston, 1992; Kuh and Yoav, 1997; Power et al., 2013). We note that there is not complete unanimity regarding whether early life conditions are important for understanding later-life health. Some studies suggest that early life factors affect later-life mortality only 'modestly' (Barbi and Vaupel, 2005) while others conclude, as we do in this article, that exposures in the early years are crucial in affecting mortality shifts among elderly individuals (Finch and Crimmins, 2004).

This article is structured by beginning with a review of the importance of ontogeny and the intrauterine environment and followed by central socially and biologically induced changes that comprise much of the biodemographic literature on early life circumstances. We begin with briefly describing the basic arguments surrounding the fetal origins hypothesis, a hypothesis that arises from work advanced by Barker (1990) and that proposes important mechanisms that have influenced much of the early life and adult mortality literature. We then turn our attention to studies that examine specific mortality effects associated with the fertility circumstances into which the child is born and early childhood conditions including the roles played by birth weight (BW), gestational age, birth order (and relatedly sibship size), parental and grandparental age, and early parental death. We also give special emphasis to a fundamental theme: the role of mortality selection, as any empirical estimates seeking to associate circumstances in early life to the chances of dying decades later presumes that the individuals in question are alive long enough to face these potentially lethal risks.

The literature on early conditions has generally been silent on the role of specific genetic or familial risks except to acknowledge the potential that these influences exist (Blackwell et al., 2001) though recent reviews point to its importance (Power et al., 2013; Gluckman et al., 2010). Increasing cross-disciplinary attention to epigenetics, the perspective that argues that gene expression (rather than the genes themselves) is affected by environmental circumstances, has also served to heighten the importance of gene–environment interactions in affecting adult health. This is evidenced by recent advocates proposing new methodologies within life course epidemiology (Strully and Mishra, 2009). A number of authors have argued that studies of early life circumstances should be incorporating not only genotype information (possibly the earliest of 'conditions') as life's starting point but also an individual's family medical history (Smith et al., 2009). Given our focus here, we do not devote any further space to this topic though we know that scholarship will only grow that uses as its conceptual focus the interplay between early environmental conditions, genomic risk, family medical history, and the epigenetics of later-life health.

Fetal Origins

As the earliest circumstance, the uterine environment for the developing fetus represents the context in which potentially profound forces exist that may have last effects in later life. This perspective, advanced by David Barker (Barker, 1990) building on early work by Forsdahl (Forsdahl, 1977) and frequently described as the fetal origins hypothesis, theorizes that there are specific or critical periods during development *in utero* that are especially susceptible to adverse developmental effects due to poor nutrition that may then alter mortality risks many decades later in adulthood. A central element of this theory argues that expectant mothers, when living conditions are compromised due to limited access to food, create a uterine environment that affects the development of her fetus so that the child will be prepared or 'programmed' for the very same environment where resources are scarce.

The resultant "thrifty phenotype hypothesis" (Hales and Barker, 2001) states that newborns experiencing poor fetal growth (and therefore are generally low BW) will be more likely to experience Type 2 diabetes and the metabolic syndrome in adulthood as a consequence of poor nutrition *in utero*. Children born under these conditions who acquired insulin resistance as an adaptive response to limited nutritional resources that helped them *in utero* may actually be worse off when prenatal undernutrition is a poor predictor of nutritional availability later in life. These responses may be adaptive in the short run but deleterious in the long run and may lead to accelerated adult mortality (Gluckman et al., 2010; Barker, 1995).

Arguably one of the most iconic human studies that investigates the fetal origins hypothesis is related to the late effects related to starvation and malnutrition initiated by the 1944–45 Dutch Hunger Winter during World War II brought about by a blockade by the German army as well as a national railway strike (Lumey et al., 2011). Some adverse outcomes have been associated with *in utero* exposure related to this historical event period, including cardiovascular disease (CVD) and elevated body mass index (Painter et al., 2005). The impact of undernutrition *in utero* has not been consistently associated with adult mortality risks thus far despite the establishment of an association of cardiovascular and diabetes risks. It may simply be too soon to know if mortality effects are evident among the adults from this population (Lumey et al., 2011). In other population-based nutrition studies, excess mortality for females exposed to undernutrition in early gestation was reported.

The inconsistent pattern of findings may be related to the nature of the famine in terms of duration and age of exposure which may have led to variation in gender-specific findings. The physiological changes associated with exposure to undernutrition *in utero* may be sensitive to the timing and duration of the insult. Different fetal organs grow at different rates, making the timing of the insult an important aspect to take into account. Lack of proper nutrition during the period around conception may adversely affect placental development (Barker et al., 2010). A recent study of adult mortality in men and women by trimester of exposure to the Dutch famine found that females exposed to famine in the first trimester had increased risk of adult mortality, cardiovascular mortality, and cancer mortality compared to the unexposed. Exposure to undernutrition in the second trimester may lead to decreased renal function in adulthood and an increased risk for obstructive airway disease (Lopuhaa et al., 2000; Roseboom et al., 2006). Late-gestational exposure has been linked to impaired glucose tolerance (Ravelli et al., 1998).

Gender differences in the effects of undernutrition may be the result of differential and innate frailties between males and females as well as gendered mortality selection. As males have higher fetal mortality rates, these male embryos may be more apt to experience the adverse intrauterine effects than the more robust female fetuses. Accordingly, men may have greater excess mortality in adulthood. Studies of the Dutch Potato Famine 1846–47 show significant excess mortality due to undernutrition *in utero* but only for males. A study of Utah pioneers that examined prenatal exposures to food shortage showed an association between undernutrition *in utero* and adult mortality with effects varying by gestational period of exposure and gender (Hanson and Smith, 2013).

The lack of clear and consistent later-life mortality effects of *in utero* undernutrition may reflect mortality selection where only the more robust survive to adulthood (Hawkes et al., 2012; Elo and Preston, 1992). Well-nourished cohorts would not experience mortality selection pressure when its members were young leading to unfavorable adult mortality risks in relation to cohorts exposed to undernutrition *in utero* and infancy. The better-resourced cohort may therefore face adult mortality rates that are higher than that of the undernourished cohort, a phenomenon that may explain the scarce and uneven evidence demonstrating excess adult mortality risks.

Birth Weight and Preterm Births

The fetal origins hypothesis predicts that fetuses adapting to an adverse *in utero* environment may change the development of key organ systems, changes that predispose the child to low BW and ultimately to an increased risk of CVD, diabetes, and stroke as an adult. Accordingly, considerable work has been done specifically on the long-term health consequences of low (and high) BW children. Birth weight is a major public health issue and the percentage of U.S. children born low BW in recent decades rose from 6.8% in 1980 to 8.2% in 2009 (Archer et al., 2011). Birth weight is a serious risk factor for adult risks not only for CVD but also for some cancers. Health risks due to preterm birth are equally important with 5–10% of young people today being born preterm. Processes that underlie the association between child BW and gestational age are complex because they may involve competing influences (e.g., low BW increases CVD risk while high BW increases some cancer risks).

Birth weight is a crucial proxy for maternal nutrition that crosses the placenta that affects fetal growth or as a marker of intrauterine conditions that led to low BW (Gluckman et al., 2008). Some conclude that altered vascular physiology associated with low BW is largely irreversible

(Norman, 2008). Preterm children also face a number of adverse health outcomes as older children (Saigal and Doyle, 2008) and younger adults with respect to mortality (Swamy et al., 2008).

A recent meta-analysis of 22 studies assessed the association between BW and adult mortality from all causes, CVD or cancer (Risnes et al., 2011). For all-cause adult mortality, an increase of 1 kg of BW translated into a 6% decrease in risk, a protection that was larger (12% reduction per kg of BW) when focusing on CVD. For mortality specific to cancer, the risk associated with a kilogram increase in BW was an increase of 13%. This study demonstrated a protective association between BW and all-cause adult and cardiovascular mortality. Increase in BW was a risk factor for cancer mortality, particularly men. Some studies reporting a positive association between BW and adult cancer risk may be attributable to estrogen exposure and insulin growth factors (Lof et al., 2007).

One of the largest studies of adult survival based on a comparison between full-term and preterm births was conducted by Swamy and colleagues (Swamy et al., 2008), an important analysis given that much of the mortality analysis of preterm births focuses on infant mortality. Given data limitations, there are very few well-designed analyses of survival in the following decades extending into the adult years. Swamy and her collaborators used data from nearly 1.2 million births (singletons only) in the Medical Birth Registry of Norway who were born between 1967 and 1988. Survival was assessed for these children through 2002 such that the oldest individual could be as old as 35 years at the conclusion of the study, an unprecedented period of follow-up for a cohort containing preterm births. The cohort was truncated to births from 1967 to 1976 for assessment of educational achievement and reproductive outcomes through 2004. They stratified the preterm sample into several gestational age categories (22–27, 28–32, and 33–37 weeks). For both boys and girls in the shortest gestational age group, preterm children were shown to have an excess risk of mortality throughout childhood. For boys, the significant relative risk (RR) of mortality for preterm versus full-term births was RR = 5.3 for 1–5.9 years of age and 7.0 for 6–12.9 years of age. The comparable estimates for girls was RR = 9.7 for the younger age group (no later childhood deaths were observed in this cohort). For 28–32 weeks of gestation, the mortality rates for boys were still significant relative to full-term births but had dropped to approximately RR = 2.4 for the same childhood age groups, a result different for girls which showed no significant increases in childhood mortality. Mortality in adolescence was not affected by gestational age for either gender. These results again point to the importance of mortality selection because as the individuals age, the most susceptible are culled from the population thereby leaving a more homogeneous and healthy subpopulation. One of the challenges of studying preterm births relates to its confound with BW. Delineating their unique contributions to adult mortality risks must be done well since they may involve different mechanisms (e.g., low BW and compromised or adaptive development, preterm birth, and maternal infections) (Liew et al., 2008).

Sibship Size and Birth Order

One of the earliest family structure characteristics is established by a child's position within a sibship. Life chances and adult mortality risks have been hypothesized to be sensitive to these two distinct but correlated characteristics. The number of siblings has been found to be positively associated with lower educational achievement and unhealthy lifestyle choices which may account for some of the modest but significant effects of larger sibship sizes in adult mortality risk (Smith et al., 2009; Modin, 2002), though siblings may also be a source of social support. Children with more siblings have been shown in natural fertility eras and in developing countries generally to face excess infant and childhood mortality rates which may, once again, remove the most vulnerable from the population and severe to limit the effects of sibship size on later mortality. Several studies have advocated the "resource dilution model" (Modin, 2002), which hypothesizes that parents are faced with resources constraints and that more offspring simply means a dilution of resources that may serve to adversely affect these offspring later in life.

Few studies have examined birth order and its influence on longevity. In the Modin study, higher birth-order girls were found to have excess mortality risks in relation to firstborn sisters (Modin, 2002). Firstborn children may benefit from more parental time and resources but they may also assume more adultlike duties as well. This same study indicated that a mechanism underlying this phenomenon is that firstborn children are more likely to attend college and reach higher levels of educational and occupational achievement than their siblings (Modin, 2002). Characterizing the role of birth order on adult health is an important issue to examine further since family sizes are shrinking globally making sibship size and birth order increasingly synonymous (i.e., firstborn in a one-child family).

Correlated Environments

Where a person begins will often affect where they land in terms of a range of characteristics including health, socioeconomic status (SES), and residential location. From this social 'immobility' perspective, individuals whose lives begin in disadvantaged circumstances often endure disadvantages throughout their lives, and similarly the initially advantaged will frequently remain so as they age. These ideas have been characterized in two related concepts: correlated environments and cumulative advantage (Preston et al., 1998). In the former instance, individuals starting out living in an advantaged setting (e.g., parents, neighborhoods, schools, peers) will likely enjoy 'correlated' advantages or settings throughout life. This phenomenon of resource inertia or persistence is perhaps most apparent in the case of residential stability: the person who ages in place will be subjected to the same or very similar forces in childhood as in adulthood since these forces persist in the place. In a similar fashion, children born to wealthy parents will enjoy the benefits of that wealth when they are children as well as when they age into adulthood (George, 2005). This phenomenon has been examined in a recent analysis of SES

over the life course and its effects on adult mortality in Finland (Elo et al., 2013).

Cumulative advantage suggests that early differences favoring one group over another will provide opportunities to the favored group that will fortify these early advantages (Dannefer, 2003). Some of these early advantages create new environments later in life that are strongly associated with the environments present in the beginning. Accordingly, the perspectives of cumulative advantage and correlated environments share common attributes and mechanisms. In both cases, those with early deprivation are likely to endure many of the same adversities throughout life. This describes a mechanism that is counter to the idea that early susceptibilities per se lead to subsequent poor health. The idea of cumulative advantage has been codified in various compendia (Kuh and Yoav, 1997), and applied to explain how cumulative exposures affect later-life health and socioeconomic outcomes (Dannefer, 2003), myocardial infarctions (O'Rand and Hamil-Luker, 2005), self-rated health (Mirowsky and Ross, 2008), and premature mortality (Melchior et al., 2006). Geronimus and colleagues have presented related ideas with respect to the weathering hypothesis which argues that some groups (e.g., African-Americans) experience adverse health effects and increases in allostatic load due to the cumulative impact of repeated encounters with social, economic, or political exclusion and deprivation (Geronimus et al., 2006; Geronimus, 1992).

Parental and Grandparental Age at Birth

There is growing evidence that an individual's reproductive history plays a role in affecting their risk of later-life mortality. Specifically, late-fertile mothers, and to a lesser extent, late-fertile fathers, have been shown to have better survival past the age of 50 years in relation to other individuals. These findings are based on populations when technological advances that could artificially extend ages of female reproduction as well as longevity are largely absent. The question is whether later fertility confers a survival advantage for the adult offspring that are the outcome of this late fertility. In considering this topic, it is equally important to examine the role played by young parental ages given reports of adverse consequences encountered by children born to these parents (Henretta, 2007).

There are several proposed mechanisms that link later parental age and adult offspring survival. First, some investigators have argued that adult offspring of late-fertile fathers will have reduced longevity in relation to their counterparts born to younger fathers. Based on the findings of Gavrilov and Gavrilova (Gavrilov and Gavrilova, 1997), the proposed association suggested by this alternative hypothesis should be especially pronounced among female offspring. They suggest that daughters of older fathers experience a significantly lower adult survival. Other studies report detrimental effects of late fatherhood on offspring longevity, most of which are associated with the putative increase in mutation rates with paternal age for specific conditions (Smith et al., 2009). Among these conditions are dwarfism, congenital heart defects, acute lymphoblastic leukemia, and schizophrenia as well as autism.

For mothers, increasing age translates into declining fecundity and an enhanced chance of obstetric complications. This reduction in fecundity generally begins around the age of 30 years and is related to the growing damage to DNA in germ cells and accordingly lower quality oocytes. This age-related pattern of fecundity plays a key role in understanding the association between maternal age and offspring health as noted by the increased risk of bearing a child with Down syndrome as maternal age increases.

Some have argued that late paternal age may result in beneficial effects for offspring. Offspring of late-fertile fathers have been found to be better off because these fathers are socially established, more financially stable, and better able to provide for their families (Mare and Tzeng, 1989). This suggests that these 'mature' fathers would be of great benefit to their children and would lead to better offspring survival. Analytically, this position indicates that it is important to control for the effects of parental SES so as to generate separate estimates of parental age from a putative effects of high SES.

Not all investigations find an association between late parental age and offspring survival health. Two recent studies using representative of the United States and Canada found little evidence that older mothers have adult children with poorer health or elevated mortality (Hubbard et al., 2009; Myrskyla and Fenelon, 2012).

Offspring born to very young parents are known to suffer adverse consequences associated with higher levels of material deprivation associated with early parenthood. This can occur for many reasons including reduced levels of education of their parents and the strong likelihood that there will be many subsequent births which further raises the prospects of poverty for children of teen parents. While the literature unfortunately focuses on contemporary populations, it is nonetheless informative in that it strongly suggests that children of teen mothers would have encountered adversity in times past. However, for populations living in natural fertility conditions where agricultural conditions prevailed, many children can be an important asset such that early and frequent childbearing could enhance the family's economic circumstances.

Finally, late reproduction has consequences for the offspring in terms of the years that parents are alive and available to these offspring. Specifically, a child born to older parents will likely see these parents die at an earlier age than a child born to younger parents. Evidence exists showing that adult offspring whose parents died when the offspring was young (<18) were themselves at increased risk of adult mortality (Smith et al., 2009). Moreover, the child's age when that child loses a parent to death may be a reflection of some aspect of shared family longevity.

An additional inferential challenge exists for studies attempting to establish a relationship between late parental age and offspring adult mortality: SES. It is well established that increasing levels of SES are associated with improving health, adult health, and survival. Children born to older parents will likely be joining families with greater resources.

Research on parental age and offspring mortality is associated with the idea that very early or very late ages at reproduction among grandparents may also have an effect on the longevity of their grandchildren. This work suggest that if the child's own parents were conceived by very young or very old

parents (i.e., the child's grandparents), does that child face differential survival chances effects in relation to offspring born to mothers and fathers who themselves were born to parents when they were at normative reproductive ages, all independent of maternal and paternal ages? Several possible mechanisms may link advanced grandparental and parental age on grandchild survival. For example, Eisenberg (Eisenberg et al., 2012) showed that grandchildren of older paternal grandfathers at the birth of fathers have longer telomeres. This suggests that these older grandfathers may actually enhance the survival of their grandchildren as longer telomeres are associated with better survival. This argues for a protective effect of being a grandchild of an older paternal grandfather. Recent studies have shown that advanced grandmaternal age may also affect the survival prospects for their grandchildren (independent of maternal age), particularly for reasons associated with birth defects such as Down syndrome (Aagesen et al., 1984; Malini and Ramachandra, 2006). The argument for this association is based on the idea that grandmothers conceiving daughters at advanced ages are carrying female fetuses who, during gestation, will be developing ova that will be later fertilized leading to the subsequent grandchildren. If the chromosomal anomalies associated with older grandmaternal eggs that were present for the ego's mother's birth, then it is possible that these anomalies may also affect the quality of the store of eggs being developed by ego's mother when she was a fetus.

Early Death of a Parent

This article has focused on events proximate to the birth of the individual in question. In this section, we turn our attention to a somewhat later familial event, death of a parent. This is introduced partly because of its importance to the life course literature and its undeniable importance to a child's life but also because it is closely related to the domains discussed thus far. For example, undernourished mothers and parents bearing children later in life are also at greater risk of dying when the child is still young.

A number of investigations have examined how early parental death has increased the risk of adverse health outcomes later in life (Chang et al., 2011). Younger children in these bereaved families are, therefore, likely to experience deprivations (e.g., the loss of social and economic support) such as those encountered by the surviving parent. Certainly childhood and adolescence are phases where psychological and physical change can be tumultuous ordinarily – a loss of a parent at these ages could therefore yield dramatic adverse and lasting effects. Studies of historical populations show how important parental death was for the survival of children (van Poppel, 2000). In a study of mortality in a historic cohort where all subjects were born in the latter half of the nineteenth century, there was no empirical support for excess mortality associated with early parental death, *ceterus paribus* (Smith et al., 2009). In studies that examine this question, parental death may be an indicator of environmental conditions that led to both a parent's death and that also adversely affected the adult offspring's risk of premature death.

A number of investigations have examined specific late-age conditions instead of all all-cause mortality. In studies of Alzheimer's disease (AD) that examine the adverse effects of early parental death that use the Utah Population Database, an increased risk of AD risk past the age of 65 years was found if an individual lost their parents to death early in life (Norton et al., 2011). In addition, a few well-done population-based investigations have also considered how early life parental death may alter the suicide risk of their adult offspring. Early death of a mother has been associated with an excess risk for suicide (Agerbo et al., 2002; Gravseth et al., 2010). A Swedish registry-based study examining data from 1969 to 2004 (Wilcox et al., 2010) found the risk of suicide for the offspring was elevated when parents committed suicide but not for other causes. Niederkrotenthaler and coauthors also used Swedish data and reported evidence that parent death early in the child's life increases their risk of suicide (Niederkrotenthaler et al., 2012). These studies illustrate the centrality of parental survival with respect to altering the probabilities for a long and healthy life for their offspring and highlight the complex set of factors that complicate these associations, especially the causes and contexts of the parent's death.

With early parental death, remarriage of the surviving parent is a real prospect that may affect adult offspring mortality risk. In the AD study noted earlier, they reported that early parental death elevated the adult offspring risk of AD after the age of 65 years. A historical Swedish study also showed a similar protective effect for all-cause mortality with respect to remarriage of the surviving spouse. In short, we expect remarriage of the widowed parent may provide additional resources that link parental death to suicide risk (Andersson et al., 1996).

Mortality Selection

Demographers and evolutionary biologist have addressed early life conditions and their association with aging and adult mortality at the population level. As an alternative to the individual level analyses discussed thus far, the population perspective examines parameters designed to depict broad characteristics of mortality that measure fundamental patterns in a defined society. A long-standing classic and useful tool to examine these issues is the Gompertz model. The Gompertz equation has two components that address the two central elements of this article: $m(x) = m(0)\exp(bx)$. Here, the mortality rate at any age x (i.e., $m(x)$) is a function of two parts. The first, $m(0)$, summarizes environmental or extrinsic exposures in the population that especially dominate during childhood; nonetheless, it describes living conditions and external threats that apply to all members of a population and that are not generally viewed to be related to aging per se. The second component, $\exp(bx)$, has a parameter b that measures how $m(x)$ changes with increasing age x. The parameter b is positive indicating that the susceptibility to death grows with age due to the accumulation of stress, mutation load, disease, and senescence. This is often described as 'intrinsic mortality' arising from physiological deterioration starting after maturity (Hawkes et al., 2012).

Examining the relationship between broader environmental risks, which dominate the mortality risk of the young as measured by $m(0)$, and the rate of mortality increase by age as measured by $\exp(bx)$, helps to better highlight the selection

mechanisms that link early life circumstance to subsequent life chances years later. In general, these two mortality parameters are inversely related (Hawkes et al., 2012). In their classic treatment of this question, Strehler and Mildvan in 1960 studied the association of the two Gompertz parameters and found support for an inverse relationship between them using life tables from 1955 (Strehler, 2000). These results have been replicated across a diverse set of populations and have been termed the compensation law of mortality which states that "High mortality rates in disadvantaged populations … are compensated for by low apparent 'aging rates'…" (Gavrilov and Gavrilova, 2001).

This body of work raises one of the key conundrums of the life course epidemiological and biodemographic approach linking early years to later years. Our ability to see a later-life health and survival consequence presumes that the individuals in question are alive and still in the population. Demographers often use data that have been subjected to various forms of nonrandom selection (e.g., Health and Retirement Survey, AHEAD Study). A study of later-life mortality requires that the individual lives to an age where health and subsequent survival can be observed. Having complete records of entire populations (e.g., genealogies or longstanding population registries) where a person's life and its events are depicted from birth to death gives us the opportunity to observe and understand who has been selected out of the subpopulation of interest and to make assessments of any selection biases created by the resulting mortality selection.

The fundamental point, then, is that all populations are characterized by heterogeneity in survival prospects since individual members have varying levels of frailty and as the force of mortality selection changes, different sets of survivors (but survivors nonetheless) will comprise the older age subpopulation. If extrinsic mortality risks increase, the more susceptible individuals will have left the population at a young age leaving a class of older individuals who were likely always at lower risk. Under this general differential heterogeneity hypothesis, scholars of late effects of early life exposures are making their assessments based on a nonrandom subset of the population and often without attempting to examine how the selection may affect the findings. If, in the extreme, the early life exposure in question is so lethal, then very few individuals will be observed at older ages with the exposure and equally as important, fewer yet will be experiencing the health outcome of interest. Of course, this selection process is at play even further back in time in terms of conceptions and spontaneous abortions – women who suffer from infections and malnutrition are less likely to conceive or carry their children to term. These too are selection processes that obscure our view when we seek to see associations between early and later-life events.

Conclusion

The linkages and pathways connecting prenatal and childhood conditions to adult mortality risks are manifold and complex. In this article, a number of specific traits, risk factors, and processes have been outlined that address these broad scientific questions. As this literature is large and diverse, we were only able to address a sampling of the empirical findings while simultaneously offering general themes and controversies. While this research area has been the focus of a number of studies, consensus regarding how and which early life conditions contribute to these health and longevity differentials remains elusive. This state of affairs is explicable given the myriad associations linking factors occurring earlier in life to numerous adult-onset diseases and premature mortality. We conclude by encouraging other investigators about the importance of studying multiple exposures since a more complete portrayal and understanding of the complex linkages connecting past circumstances to later health outcomes requires a large and conceptually driven set of measures of adversity and privilege and health endpoints.

Early Memory Development and Cultural Variations

Abstract

While infants' memory has been studied traditionally in adults through retrospective research, methodology in developmental psychology has made tremendous progress in the last decades so that nowadays infants' memory can be assessed directly. Following the taxonomy that separates a nondeclarative from a declarative memory system, different early memory aspects are under study. Although most evidence for early memory development exists for the Western cultural approach, there is a growing body of research about memory development in different cultures which is discussed in this article.

Neonatal and Infant Memory

The interest for infant memory has a long and extensive tradition in developmental psychology. Since Freud proposed that infant experiences strongly influence adult behavior, the infancy period is conceptualized as being very important for cognitive and behavioral development. Early developmental theories endowed newborns and infants with no or very limited memory capacities. Freud reasoned, for example, that early memories linger in an unconscious state and thus cannot be recalled. Similarly, Piaget assumed that infants younger than 18 months are not able to form mental representations precluding the construction of 'memory in a strict sense,' i.e., memories that are consciously and deliberately retrievable. In addition, the growing popularity of the infantile amnesia phenomenon, i.e., the typically observed inability of adults to remember personal life experiences having occurred before the age of 3.5 years (Bauer, 2007), increased the interest in infant memory development. For a long time, however, infant memory was underestimated and rather subject of theoretical reasoning as well as speculation than scientific evidence as a lack of age-appropriate methods precluded studying early memory capacities empirically.

By introducing the visual paired comparison paradigm, Fantz paved the way for a groundbreaking new empirical, behavior-based research program on cognitive and memory processes in early infancy. In a seminal study, Fantz (1964) demonstrated that infants between 2 and 6 months of age habituate to a repeatedly presented visual stimulus, i.e., they successively show decreased visual attention. In a visual test after habituation, infants prefer a novel stimulus to the simultaneously presented habituated, familiar stimulus. This finding indicates basic memory capacities, as a familiar stimulus needs to be represented in memory to be compared with a novel stimulus. Since this pioneering research, additional behavioral paradigms testing various aspects of memory in infants have been developed. These paradigms, rather directly assessing memory, are used to systematically describe the characteristics of the memory system of neonatal and young children (see section Direct Assessment of Memory in Infants and Young Children from Different Cultural Backgrounds).

A significant limitation of memory research in infants and preverbal children, as for psychological research in general, however, is that most of the memory studies conducted so far relate to newborns, infants, and preverbal children from a homogeneous sociocultural background, namely those living in educated and affluent families from Western, democratic, (post-) industrialized societies (see also Leichtman, 2011). Hence, the study of the effects of cultural contexts on memory systems' development in the early years is still in its infancy and future research should increasingly take into account cross-cultural differences and consistencies of newborn, infant, and preverbal children's memory development.

The present article therefore, first, reviews the memory system model used in state-of-the-art newborn and infant memory research (see Section Memory System Model). Secondly, in the next section two different sociocultural background models mostly used to describe cross-cultural memory research studies with infants are presented (see Section Cultural Models). Thirdly, the article describes different memory paradigms used to assess memory in infants and describes findings from cross-cultural developmental studies (see Section Cultural Approaches and Early Memory Development). Finally, some future research perspectives for cross-cultural memory research are outlined (see Sections Concluding Remarks and an Attempt to Forecast the Future of Cross-Cultural Research on Early Memory Development).

Memory System Model

The common theoretical memory systems perspective in infant memory research is the distinction between *nondeclarative (implicit)* and *declarative (explicit)* memory. Declarative memory includes explicit recognition or recall of facts and events, and thus represents the capacity to virtually remember, whereas nondeclarative memory comprises forms of memory that function without conscious awareness or deliberate retrieval such as priming, procedural or skill learning, and conditioning. Declarative memory is further divided into semantic memory referring to a person's general knowledge about the world including facts, concepts, and vocabulary, and episodic memory representing specific personal experiences which are associated with a particular learning context (i.e., place and time). Given this distinction, it can be assumed that due to their reliance on conscious experiences declarative memory is affected significantly stronger by sociocultural factors than nondeclarative memory processes (cf Leichtman, 2011).

Cultural Models

Growing up in a culture means being surrounded by socialization agents (e.g., the mother, other women, relatives, other caregivers) or being in close contact with individuals who, according to the specific cultural perspective, typically share their time with babies and children (e.g., siblings, same-aged peers, grandparents, teachers) either in a social institution (e.g., kindergarten) or rather in the familial context. Self-evidently, the interactions between developing individuals and significant socialization agents follow specific cultural conceptions and practices (e.g., ideas about the specific nature of children; concepts about child education; specific socialization goals; conceptions about acquisition of developmental milestones, values, and competences). In addition, specific cultural backgrounds are tied to specific physical environments characterized by typical living things (e.g., plants, animals) and determined by typical activities and routines involving culture-specific tools and artifacts (e.g., navigating a ship, planting something, visiting a restaurant; toys, needles, bowls, or PCs). Both physical and cultural world can be seen as complementary constraints shaping individual development. Beyond doubt, these micro- and macrocultural environments differ significantly for individuals growing up at different places in the world.

Culture and Cognitive Development in General

A traditional research program compares how infants, children, and adults from different cultural backgrounds typically solve cognitive tasks (e.g., mathematical thinking; category-based reasoning; holistic vs analytic reasoning; causal explanation; attend similarity and relationship between objects and rules). Moreover, in a related research program, cultural groups are studied in times of dramatic cultural changes. In the pioneering work of Luria, for example, syllogistic reasoning of different groups of Uzbek peasants living in Central Asia were compared during times of dramatic social and economic changes. Some of these groups lived traditionally and were illiterate while others attended schools for a different number of years. Cognitive changes significantly differing between cultures were described (see Nisbett and Norenzayan, 2002; for a detailed review). Memory processes, however, were not included in this traditional research program. As especially explicit memory is closely linked to other cognitive processes, the aforementioned studies and findings imply that memory processes should also vary as a function of cultural context.

Two Different Basic Cultural Approaches

In traditional studies on cultural influences on cognitive processes only rough ideas were sketched to characterize cultural contexts and to describe cultural differences. In recent years, however, suggestions to systematically distinguish basic cultural paradigms have been made. Cultural paradigms manifest in parental ethno-theories (i.e., beliefs, values, and practices of caretakers about child education and upbringing) resulting in different everyday, culture-specific infant experiences regarding, for example, motor stimulation, object exposure, and conversational styles. It is often stressed that parental ethno-theories differ according to infant and children's developmental milestones.

A first cultural approach to describe basic cultural models differentiates between two cultural developmental pathways, i.e., the pathway of interdependence versus independence. Within the interdependent cultural model, typically observed in rural agrarian areas in Cameroon or India, for example (Keller et al., 2006), essential socialization goals are the adaptation to family system values as social familial cooperative skills are crucial for surviving. In contrast, the independence cultural model, typically found in urban Western technological societies like Germany, other European countries, and the US emphasizes autonomous individual development, exploration ability, and personal achievement.

A second cultural approach distinguishes a Western Euro-Caucasian-American cultural style from an East Asia cultural style, typically observed in China, Japan, or Korea (e.g., Gutchess and Indeck, 2009). These cultural styles lead to cultural differences with respect to social development domains, mostly. Whereas from a Western Euro-Caucasian-American cultural style, the development of an autonomous self with unique personal characteristics is a central developmental goal, individuals raised in the East Asia cultural style perceive themselves in terms of their interpersonal relationships and their social roles. Next to social domains, cognitive domains are also determined by these different cultural styles. Individuals from Western societies tend to focus on objects, category relatedness, and self-relevant aspects of the situation. In contrast, individuals from East Asian cultures are more attracted by details of the context, from similarities between stimuli in a given situation as well as from information that is relevant for the group.

Cultural Approaches and Early Memory Development

Two methodological tools are currently used to study memory development in young children. On the one hand, the indirect assessment method assesses the emergence of memory by asking adults or older children to recollect their earliest memories. On the other hand, the direct assessment method, developed and used in the last couple of years, directly assesses memory in young children and even infants via different behavioral methods. Both research programs have also been used to study culture-specific early memory differences.

Culture-Specific Early Memories Assessed via the Indirect Assessment Method

The indirect assessment method has already been used to describe early memories for a long time (e.g., Freud). This research program was recently expanded in that the influence of culture for recollected memories was studied. Typically, adults from a Euro-Caucasian-American cultural background are compared with adults from Asian cultures in this research field. A significant limitation of this research methodology is the fact that memory contents have to be recollected verbally allowing to test only declarative memory aspects. Until now, research focuses on two closely related memory aspects.

On the one hand the phenomenon of *childhood amnesia* is cross-culturally assessed by describing the time when individuals from different cultural backgrounds are able to verbally report their first memories (e.g., MacDonald et al., 2000; Wang, 2008). On the other hand, a series of studies analyzed effects of cultural background on the development of individual's self-view. Referring to the memory model outlined above, this research program relates to the emergence and the development of *autobiographical memory* (Wang, 2011). Within both research programs, subjects are asked to explicitly and verbally recollect specific events and episodes. Besides memory processes, a couple of higher cognitive processes in general (e.g., language development, memory awareness, deliberate verbal recollection) are necessary as precondition to represent personal events in memory or to recollect the (possibly) stored memory entities.

Wang (2008) reviews recent studies looking at childhood amnesia from such a sociocultural perspective. By typically comparing the availability of earliest memories of individuals growing up in European American cultures versus different East Asian cultures (China, Taiwan, Korea), the universality or culture specificity of childhood amnesia was studied. In addition, in some studies, adults from a different cultural background but living in the same society have been compared (e.g., New Zealand European, New Zealand Asian, New Zealand Maori; MacDonald et al., 2000). Moreover, studies testing mostly young adults used different recollection methods assessing earliest memories (e.g., free recall, memory fluency test, word cue method), thereby testing, to which amount childhood amnesia is a function of low accessibility of early memories.

Although studies found some variability in the age of earliest memories as a function of recollection methods in that facilitative cues trigger earlier memories retrieval, cross-cultural studies consistently observed differences in the age of earliest memories. In line with theoretical reasoning, individuals growing up in a European or American culture remembered earliest memories between approx. 5 and 17 months earlier in their personal life as had individuals growing up in East Asia cultures.

Although these findings show that individuals from European American cultures seem to have earlier autobiographical memories, results also demonstrated culture-specific, qualitative differences of recollected episodes. In this respect, the character of adult's self-related stories and how adult's knowledge about the self is conceptualized differs significantly across cultural models. Euro-American adults, for example, recollect more specific, unique events and episodes from their lives that are highly centered to the self as unique individual (e.g., Leichtman, 2011; Wang, 2011). In contrast, adult Asians provided more generic, less detailed episodes that related to their social roles, their social relatedness, and their membership in specific groups. The dominant view about the emergence of these culture-specific differences in episodic memory has to do with the content and the degree of elaboration of memory conversation in early parent–child conversation. European American mothers held very elaborated memory conversations with their young children in which they ask them about their thinking, their feelings, their interests, thus providing an opportunity for the children to develop detailed memory episodes together with self-views as autonomous and unique individuals ('child-centered approach,' Wang, 2011). In contrast, East Asian mothers do not deliver that much detail in memory conversations with their children. Moreover, social interactions, moral rules, and behavioral expectations are often emphasized by Asian mothers ('mother-centered approach,' Wang, 2011). It is assumed that this mother-centered type of conversation may facilitate the recollection of events related to others and not so much the early storage of self-related information.

The theoretical assumption that mother guided memory talk is the basis of the more elaborated autobiographical memories of young European American children is strengthened by training studies. It has been found that young children of mothers, who were trained to be especially elaborative in their memory dialogue, provided more elaborative autobiographical memories than children in a control group of mothers who did not receive such a training (see Fivush, 2009).

Direct Assessment of Memory in Infants and Young Children from Different Cultural Backgrounds

In contrast to the measurement of memory in adults who can be asked to recollect information, infant memory research has to revert to methods based on simple behaviors, thereby requiring tasks that prompt the encoding, storage, and retrieval of information. Thus, memory is inferred from behavioral changes resulting from previous engagement with given materials. With regard to their mnemonic demands, these techniques can be classified as implicit or explicit memory tasks.

Implicit Memory

One major paradigm to assess implicit memory abilities in infancy is the *visual paired comparison paradigm* that involves exposing the infant to pairs of a stimulus and then showing this familiarized stimulus simultaneously with a novel one. Similarly, in the visual *habituation paradigm*, a stimulus is presented sequentially and either after fixation time decreased to a pre-set criterion (infant-controlled) or after a particular number of presentation trials (fixed), a novel stimulus is presented. In both paradigms, infants' looking time is assessed and a difference in fixation times to familiar compared to novel stimuli is taken as a measure of recognition memory. The most influential model, the comparator model, assumes that during the task, a memory trace of the visual stimulus is gradually constructed, information about the stimulus is retrieved from memory, and this memory traced is compared with the current visual input. Theoretically, it is still debated whether infants' preferences measure adult-like explicit memory capacities or implicit memory. Notwithstanding this debate, the assessment of infants' visual preferences yielded evidence for immediate as well as delayed recognition capacities showing an age-related increase in recognition memory during infancy. For example, Bushnell (2001) found that newborns prefer their mother's face to the face of an unfamiliar woman even if they had not seen their mother's face for 15 min. In addition, using the habituation method, Pascalis et al. (1998) demonstrated that 4-month-old infants are already capable of recognizing a previously unfamiliar face after a delay of 24 h.

Furthermore, the influence of stimulus complexity and meaning was demonstrated because 5-month-olds retain abstract patterns for 48 h and recognize faces after a 2-week retention interval (Fagan, 1990).

Studies applying visual preference paradigms within different cultural environments found no differences regarding rate of habituation, exhibition of novelty preference, or different measures of visual attention, such as fixation time, in infants, toddlers, and young children (e.g., Kennedy et al., 2008).

Classical and operant conditioning methods are also frequently applied to study learning and memory in infancy. In a *classical conditioning* study by Little et al. (1984), 10- to 30-day-old infants' eyelid response was conditioned by pairing an air puff (unconditioned stimulus) with a tone (neutral stimulus). After repeated presentations of these coupled stimuli, infants showed an eyelid response (conditioned response) when only the tone (conditioned stimulus) was presented, and 20-day-old infants exhibited savings even 10 days after the conditioning session in terms of requiring shorter presentations of the paired stimuli to evoke the conditioned response. Because neuropsychological studies confirm that classical conditioning is based on cerebellar processes, it can be concluded that it taps implicit memory.

Rovee-Collier and collaborators developed the mobile conjugate reinforcement procedure, an *operant conditioning* method to study learning and retention in 2- to 6-month-old infants. Within the mobile task, one leg of the infant is connected to an overhead mobile. In a first baseline phase, leg kicks do not generate movement of the mobile, whereas in the following reinforcement phase, leg kicks produce mobile movement. Learning of the contingency between own motor activity and movement of the mobile is indicated by an increased kick rate during reinforcement compared with baseline activity. The train task was developed as an age-adapted variant to assess whether infants older than 6 months of age learn to press a lever to move a miniature train. Studies applying the mobile and the train task have found that the duration of long-term memory increases linearly within the first two years of life: While 2-month-old infants show retention up to 2 days after training, those aged 6 months remember the mobile for 2 weeks, and 18-month-old infants retain the contingency over an interval of 13 weeks (for an overview, see Hartshorn et al., 1998). By implementing a reminder, the retention of 3-month-old infants was increased up to 4 weeks (Rovee-Collier, 1995). However, memory assessed by this task is quite specific because retention of the contingency is disrupted if training and test situation differ in any detail (e.g., Rovee and Fagen, 1976). Since learning of the contingency between motor activity and a visual event is attended by cerebellar activation, it is assumed to represent implicit memory (Nelson, 2002). However, Rovee-Collier (1997) argues that recognizing the mobile after the delay is expressed by a motor response and thus reflects an early form of explicit memory.

In a study by Graf et al. (2012), the mobile task was applied to assess contingency learning and associative memory in 3-month-old Cameroonian Nso farmer and German middle-class infants. Infants participated in two sessions at intervals of 24 h and when they reached a pre-set learning criterion during reinforcement they were tested for immediate and long-term retention. Results showed that 3-month-old infants in both cultural contexts are able to learn and to retain the relation between own leg kicks and the visual event indicated by an increased kick rate after reinforcement as well as after the 24 h delay compared with the baseline level of response. Nevertheless, culture-specific experiences influenced performance in this task: Although a higher proportion of Cameroonian Nso infants reached the critical increase during reinforcement and were thus classified as learners, this difference was not attributable to the advanced gross motor abilities of Nso infants but instead based on the level of baseline response. Depending on culture-typical experiences in motor handling (lying on the back with arms and legs free to move in Germany vs being carried in a sitting position in close body contact restricting movement of the limbs in Cameroon), German middle-class infants showed a higher level of baseline activity compared with Cameroonian Nso farmer infants impeding the achievement of the learning criterion. To conclude, this study demonstrated that cultural differences concerning infants' everyday experiences influence the level of motor response and hence affect learning performance in this task which is why characteristics of the context ought to be considered before applying this task across different cultural environments. With respect to the likely influence of culture on particular aspects of memory, this study confirms the assumption that implicit memory processes, here indicated by learning of the contingency and recognition of the mobile after the delay, do not display cultural memory differences.

Priming is also applied to assess implicit memory in verbal children and adults. In a prototypical priming task, the picture completion task, pictures are presented and after a delay ranging from seconds to months, the pictures are presented again but in a fragmented mode (i.e., only a fraction of information is presented). Priming is indicated when prior exposure to the pictures facilitates their subsequent recognition which can be measured by the reaction time or by the level of information required to name (i.e., to recognize) the picture. Regarding priming in early childhood, Gollin (1960), for example, demonstrated that 30- to 41-month-old children show a priming effect after a delay of 1 week. Several studies comparing priming in children at different ages and adults found no age-related effects (e.g., Parkin and Streete, 1988). Although priming as an implicit memory task is not assumed to be influenced by cultural factors, studies demonstrating its universality across cultures are largely missing.

An exception is the study by Vöhringer et al. (in preparation) who used a picture completion task to assess implicit memory in 3;4-year-old German middle-class and Cameroonian Nso children. Results showed that children from both cultural contexts exhibited a priming effect indicated by faster recognition of a prime (a picture they saw during a priming phase) compared to a nonprime. German middle-class children showed a higher recognition speed than Cameroonian Nso farmer children, potentially relying on extended experiences with two-dimensional pictures. Calculating a difference score between recognition speed of primes versus no-primes, however, revealed no differences between children from the two cultural contexts. To sum up, this study showed that although

recognition speed differs across cultural contexts, priming (implicit memory) is not affected by cultural context.

Taken together, results from cross-cultural studies show that visual paired comparison, habituation, mobile, and priming paradigms are only slightly or not influenced by culture-specific factors. These findings strengthen the theoretical idea that these tasks tap implicit memory processes.

Explicit Memory

A widely accepted instrument to assess memory in infants and toddlers is the *deferred imitation* task. In this task, the infant is demonstrated object-related target actions by a model. After a delay of minutes, hours, or even days, the infant has the opportunity to play with the objects and target action imitation behavior is observed. Memory thereby is inferred if infants reproduce a higher number of target actions after demonstration compared to spontaneous production of target actions. Spontaneous production of target actions is either assessed in a baseline phase before demonstration or via an independent control group receiving no demonstration of target actions. Theoretical reasoning and a series of experimental and clinical findings indicate that deferred imitation assesses declarative memory. In deferred imitation tasks, for example, subject transfer visually observed behavior into a specific motor output without prior practice (cross-modal character of the task). In clinical studies, results showed that patients with amnesia exhibit disrupted deferred imitation performance (see Mandler, 2004; for overview).

Numerous studies using the deferred imitation task found that retention increases from 24 h in 6 month olds to 4 months in infants who were presented the target actions at 16 months of age (Barr et al., 1996; Meltzoff, 1995). Moreover, it was demonstrated that the flexibility of infants' memory also increases with age as 12- in contrast to 6-month-old infants exhibited significant imitation even after a pronounced context change, i.e., a different testing room (Hayne et al., 2000).

Cross-culturally, imitation is assumed to serve as a universal learning mechanism. Goertz et al. (2011), for example, analyzed deferred imitation performance in a sample 6-month-old Cameroonian Nso and German middle-class infants. They found deferred imitation in infants from both cultural environments confirming the assumed universality of imitative learning. In a subsequent study, deferred imitation of an extended sample of Cameroonian Nso and German middle-class infants of 6 and 9 months of age was analyzed (Graf et al., 2013). It was hypothesized that with increasing age and age-associated accumulation of culture-specific experiences, cultural differences in deferred imitation would be observed.

Results show that infants at both ages and from both cultures performed more target actions after demonstration compared with the baseline phase. Furthermore, an age-related increase in the number of imitated target actions was found indicating an improvement of memory with age. Moreover, at 9 months of age, German infants showed a higher level of spontaneously performed target actions than infants in the Cameroonian sample which is assumed to rely on the different extent of object experiences. These findings add evidence to the theoretical assumption that explicit memory is influenced by characteristics of the cultural context.

Concluding Remarks and an Attempt to Forecast the Future of Cross-Cultural Research on Early Memory Development

Taken together, the findings reviewed in this article demonstrate that early explicit memory as it is found in adults' recollections is determined by the sociocultural model. The pronounced cultural developmental differences found in recollections are qualitative (self-reliance during autobiographical report studies) as well as quantitative (time where subjective memory begins) in nature.

In infants and young children, cross-cultural studies assessing the emergence of memory directly are still rare. The findings of recent studies, however, demonstrate that explicit memory (deferred imitation) is influenced stronger by cultural background than implicit memory (priming, mobile task). In line with findings from childhood, the small cultural differences are more due to qualitative than quantitative aspects of memory.

From a developmental standpoint, comparing the findings from the childhood with the infancy period indicates that sociocultural influences on implicit, explicit, and autobiographical memory increases with age, i.e., infant memory seems to rely stronger on biologically driven processes than memory during childhood years. In other words, effects of the external world (Luria, Bronfenbrenner) on memory increase in the sense of an age × culture interaction framework.

The finding that differences in memory performance increase with increasing age of children is also in line with the idea that different developmental aspects that are codeterminants of explicit memory, like language development, motor development, self-development, are also sensitive to differences in the cultural paradigms. This means, the cultural context in which an infant grows up influences memory development directly as well as indirectly.

For future cross-cultural developmental memory research, disentangling biologically driven, culturally driven, and methodologically driven effects is important to understand the true nature of memory development. This challenge also requires new, culture-fair instruments which are assessing memory performances that are asked for to the same amount within the different cultural contexts.

Abstract

Inequality has increased considerably in many Western countries over the past decades. When dealing with economic inequality as a research subject the question "inequality of what among whom?" arises. Analyses of inequality are typically concerned with the distribution of wages, earnings, or income and have been made by different strands in the literature, mainly in public and in labor economics. We summarize these strands with a special focus on earnings, which itself is the product of hourly wages and labor supply in terms of hours and weeks worked. In addition to inequality in labor market outcomes, we pay special attention to equality of opportunity.

Introduction

Inequality has increased considerably in many Western countries over the past decades. (see Gottschalk and Smeeding, 1997; Atkinson and Piketty, 2007; OECD, 2008, 2011; Atkinson, 2008; Salverda et al., 2009, for overviews.) The growing gap between rich and poor and the resulting declining middle class has become one of the main issues in policy agendas around the world. The economic crisis that followed in the aftermath of the collapse of the financial market in the United States in 2008, has rendered issues concerning the distribution of economic resources in general, and questions of the appropriateness of extremely high earnings in particular, urgent (OECD, 2011: p. 17). Austerity measures in the context of the euro crisis have recently triggered social unrest in countries like Greece and Spain where these measures are perceived to affect the poor disproportionately. The 'Occupy Wall Street' movement, which pressed policy makers for steps against growing social and economic inequality, has popularized the catchphrase "We are the 99%." Interestingly, this slogan directly refers to academic research on the increasing income share of the richest 1% of the US population, which is nowadays back to historically high levels (Piketty and Saez, 2003, 2007). Top income shares are not only increasing in the United States but also in many other countries (Piketty and Saez, 2003; Atkinson and Piketty, 2007; Atkinson et al., 2011). These examples show that the distribution of economic resources across the population is not just a matter for public debate and policy making. On the contrary, the analysis of distribution is long since "back in from the cold" (Atkinson, 1997) and has turned from "watching the grass grow" (Aaron, 1978) to become an active and relevant area of research in economics. In this article, we summarize the literature with a special focus on earnings. In addition to inequality in labor market outcomes, we pay special attention to equality of opportunity.

Why Should Economists Care about Inequality?

Economists should care about inequality even if inequality itself were not of great interest, because there are a number of important implications that come with it. For example, many economists argue that inequality is not a bad thing per se. On the contrary, inequalities in relative factor prices are fundamental to the functioning of market economies – as evidenced by the collapse of real-existing socialist economies. With special focus on labor markets, Welch (1999) emphasized that inequalities in wages are 'good' since they signal scarcities, provide incentives for investments in human capital, and compensate for different job attributes. However, Welch himself states that inequality becomes 'destructive' when society does not view effort as worthwhile and upward mobility is perceived as unlikely or even impossible. In general, public opinion in market economies shares the economists' view that absolute equality in economic outcomes is not desirable and that inequalities are, to a certain degree, not only inevitable but even necessary (Salverda et al., 2009: p. 7). However, if income differences are viewed as insurmountable, social cohesion as well as acceptance of market economy and even democracy are challenged (Stiglitz, 2012). Indeed, preferences for redistribution are systematically correlated with beliefs about the relative importance of effort and luck in the determination of outcomes. Individuals are more willing to accept income differences which are due to individual effort (or laziness) rather than exogenous circumstances or luck (Fong, 2001).

From a welfare economics perspective, a normative reason to be interested in the distribution of income is that one is actually interested in the distribution of 'well-being' and income is widely used as a proxy for well-being (Decancq et al., 2014). However, the adequacy of income as a welfare metric has recently been questioned and a consensus seems to have emerged that well-being has multiple dimensions beyond income that should be considered simultaneously – typically indicators for health, job quality, wealth, and many more (see, e.g., Stiglitz et al., 2009, for an overview). Hence, focusing on the distribution of labor earnings, which make up a substantial but not the entire part of income, is even more restrictive in terms of welfare analysis. This has to be taken into account when interpreting results on earnings inequality with respect to their policy implications.

Inequality of What among Whom?

When dealing with economic inequality as a research subject the question "inequality of what among whom?" arises (Atkinson and Bourguignon, 2001; Osberg, 2001; Goldfarb

and Leonard, 2005). The answer to the part query "among whom?" is straightforward for economists. The term 'economics' dates back to the ancient Greek word *oikos* which means household. Hence, the essence of the economics discipline is the study of the smallest unit of individuals within an economy, jointly carrying out production and consumption activities. Nevertheless, in studying earnings inequality, the unit of observation is very often the individual or the tax unit and not the actual household. In the case of a single household, all three levels of observation are identical, but this does not hold in general. For example, married couples form one household but consist of two individuals; and depending on the income tax system, the household may consist of either one or two tax units. The presence of children (or other family or household members) adds further individuals and/or tax units to the household. Given the trend toward more single persons, lower marriage, and higher divorce rates in many Western societies, the congruence between individual, tax unit, and household is changing tremendously and this has implications for the measurement of inequality.

Indeed, Armour et al. (2013) document the sensitivity of different income measures in capturing income trends. The unit of analysis (individual or tax unit vs household) and also the income concept, i.e., looking at pretax, pretransfer income versus posttax, posttransfer income, yield different results and trends. Especially, the question of whether and how capital gains are included in a measure of market income matters a lot, both for inequality levels and trends. This is related to the question of "what?," the underlying concept of economic resources, which is much more complex. Analyses of inequality are typically concerned with the distribution of wages, earnings, or income and have been made by different strands in the literature, mainly in public and in labor economics. However, there are "several steps between relative factor prices and […] disposable income among households" (Atkinson, 2003: p. 23). The most important steps in this process are the creation of gross market income from various sources and all household members, the design of the government's tax and transfer system, as well as patterns of household formation and composition.

Firstly, gross labor earnings make up the largest share of total household incomes and are an important driver of income inequality (Atkinson, 2008). A vast literature in labor economics deals with rising wage and earnings dispersion, especially for the United States (see Katz and Autor, 1999, for an overview). Common explanations are changes in the supply and demand for skills and tasks as well as changing labor market institutions and policies. Autor et al. (1998, 2008) argue that 'skill-biased' technological change (computerization) within industries has led to 'skill-upgrading' and, hence, has increased the relative demand for college-educated workers. At the same time, skill-biased technological change may not only have complemented high-level education tasks but also substituted for routine middle-level education tasks. Card and Lemieux (2001) point to shifts in the composition of the workforce with respect to education and show that a slowdown in educational attainment among younger cohorts has increased the college–high school wage gap for men due to shifts in the relative supply of highly educated men. Goldin and Katz (2008) take a longer perspective and emphasize the importance of the supply and demand of human capital in forming the distribution of earnings over the twentieth century in the United States. Acemoglu and Autor (2011, 2012) analyze the interactions among worker skills, job tasks, evolving technologies, and shifting trading opportunities.

Another strand in the labor economics literature argues that the skill-biased technological-change hypothesis put forward does not explain the evolution of other dimensions of wage inequality, including the gender and racial wage gaps and the age gradient in the return to education (Card and DiNardo, 2002). In addition to explanations referring to the supply and demand of skills, many studies have analyzed the role of labor market policies and institutions. DiNardo et al. (1996) highlight the importance of the decreasing real value of the federal minimum wage as well as the importance of deunionization in addition to labor market considerations. Fortin and Lemieux (1997) analyze the role of the decline in the real value of the minimum wage, deunionization, and economic deregulation and find that a large share of the increasing wage inequality is related to these institutional changes. Lemieux (2006) shows that the magnitude and timing of growth in residual wage inequality provide little evidence of an increase in the demand for skill due to skill-biased technological change – but points out that this is due to composition effects associated with higher within-group dispersion. In addition, differences in wages and earnings are affected by pay differentials across gender, race, occupations, or sectors. See Altonji and Blank (1999) for an overview of gender and racial pay gaps. Blau and Kahn (2000, 2006) provide overviews of the development of the gender pay differential and analyze different driving forces behind the extent and speed of reductions in the gender wage gap. Kunze (2005) analyzes the gender wage gap over different career stages in Germany. Arulampalam et al. (2007) analyze the wage gap over the entire wage distribution for European countries.

Secondly, other determinants of (wage or earnings) inequality are the tax-transfer system and patterns of household formation and composition (see Lam, 2001; Pestel, 2013, for overviews). For instance, Peichl et al. (2012) quantify how the trend toward smaller households has influenced the change in income distribution in Germany, using decomposition methods for measures of inequality, poverty, and richness. The results show that the income gap would have increased even without the demographic trend. But its level would be lower than it actually is. In addition, the demographic effect turns out to be larger for incomes before taxes and benefits, showing that there is an interaction between tax policy and household composition. Bargain et al. (forthcoming) analyze the effect of US tax policy on inequality over the period 1979–2007. The challenge in analyzing such a question lies in the fact that both taxation and pretax income distribution influence income redistribution. For instance, a progressive tax system – one in which the tax rate increases with the taxable base – has a greater effect on income redistribution when a society's gross income is more unequally distributed. In the extreme case that all taxpayers earn the same income, even a very progressive system cannot redistribute income among taxpayers. To distinguish between effects that result from taxation and those that result from changes in pretax income

distribution, the authors conducted detailed counterfactual calculations, holding constant the income distribution of one year and applying the tax system of another year. The results show that American tax policy has done little to curb inequality in the period under investigation.

Finally, total disposable household income depends on the household context, i.e., the number, composition, and characteristics of individuals actually forming households. For given wages and labor market conditions, gross earnings depend on the number of hours worked. Hence, the household context, which has changed tremendously over the past decades, determines the distribution of resources both within and across households in the economy. See, for example, Jenkins (1995), who analyzes various sources of the trend in income inequality in the U.K. during the 1970s and 1980s, including, employment, earnings, and household composition. Cancian and Reed (1998, 1999) study the role of female earnings on inequality and find an equalizing effect of increasing female labor force attachment. Burtless (1999, 2009) find that the increasing correlation between husbands' and wives' earnings as well as the increasing numbers of single-person households, has contributed to more inequality. Hyslop and Mare (2005) also find that increasing inequality in New Zealand is to a large extent driven by changes in household structure and attributes. Daly and Valletta (2006) and Martin (2006) find similar results and trends for the United States; and Schwartz (2010) addresses the increasing association between spouses' earnings as an important driver of overall inequality.

The observed distribution of disposable income is, however, not simply a matter of mechanically applying the tax and transfer schedule to gross incomes for a given household composition but the result of complex interactions between the market production of gross income (joint decisions on labor supply and savings) and the formation of households (marriage, cohabitation and fertility decisions, aging, and retirement). Therefore, it is an enormous challenge to formulate "models of the household income distribution, incorporating not only models of labor market earnings […] and the demographic factors affecting who lives with whom" (Jenkins and Micklewright, 2007: p. 19). This issue is, however, beyond the scope of this article.

Labor Earnings Inequality

Evidence for the United States

There are various measures of inequality with very different features and it is for the researcher to decide which measure is most appropriate with regard to the research subject under consideration. We do not discuss the different measures here and suggest reference to the literature (Osberg, 2001; Cowell, 2008). Instead, we follow a recent strand in the literature dealing with the contribution of top incomes to overall inequality, showing that large shares of total pretax (wage) income are increasingly concentrated among the rich (Piketty and Saez, 2003; Atkinson and Piketty, 2007; Atkinson et al., 2011). Top income shares are fairly simple and straightforward measures of inequality and easy to interpret. Although they focus by definition on small shares

Figure 1 Top 1% income shares in various OECD countries (1980 and 2009). Source: The Worlds Top Income Database.

of the population, say the top 10%, the top 1%, or even smaller fractiles of the distribution, they have been found to be very informative about overall inequality, since trends over time match very well with other inequality measures (see Leigh, 2007).

Figure 1 shows the top 1% income share for various OECD countries in 1980 and 2009. Inequality increased in all countries. Both the share in 2009 and the increase from 1980 are largest in the United States. The lowest level of inequality can be found in the Nordic countries, Norway and Sweden. Only in a few countries the increase is found to be fairly small (like Spain, France, Germany, and the Netherlands). Nevertheless, increasing inequality, especially at the top of the distribution, can be observed globally and is, therefore, an issue for researchers and policymakers in various institutional contexts.

Figure 2 shows the development of the wage income share of the top 10% in the United States starting in the 1920s, broken down into fractiles within the top decile. Before the World War II (WWII) period, the share of pretax wage income earned by the richest decile of the population was around 30%; and 8–9% was accounted for by the top 1%. During the WWII period, the top decile share dropped to around 25% (top 1%: 5–6%) and remained fairly constant until the late 1970s and early 1980s. Since then, one can observe a strong increase to almost more than 35% and, hence, exceeding the historical pre-WWII levels. Remarking is the contribution of the top 1% to this trend, which is nowadays up to around 11%, while the share of the top decile except for the top 1% (P90–P99) has only slightly increased over this period. This highlights the importance of (gross) labor income as an important driver of overall inequality, also at the very top of the US income distribution.

Components of Earnings Inequality

The overall distribution of labor earnings within a given time period, a given country, and for a specific population subgroup is determined by various factors. Typically, research on earnings inequality is concerned with a measure on an annual

Figure 2 Top 10% wage income share in the U.S. (1927–2011). Source: Piketty, T., Saez, E., 2003. Income inequality in the United States, 1913–1998. Quarterly Journal of Economics 118 (1), 1–39 and Piketty, T., Saez, E., 2007. How progressive is the US federal tax system? A historical and international perspective. Journal of Economic Perspectives 21 (1), 3–24 updated to 2012: http://elsa.berkeley.edu/~saez/TabFig2012prel.xls. Wage income includes bonuses, and profits from exercised stockoptions.

(sometimes monthly or weekly) basis. Overall earnings can be decomposed into several elements, since they are simply the product of the hourly wage rate, the number of hours worked per week, and the number of weeks worked per year:

$$\text{Annual earnings} = \frac{\text{wage}}{\text{hour}} * \frac{\text{hours}}{\text{week}} * \frac{\text{weeks worked}}{\text{year}}$$

Hence, the distribution of earnings is potentially affected by all of these components and their underlying subcomponents.

First, the wage rate reflects the conditions of the respective labor market. On the one hand, relative supply and demand for different levels of skills play an important role, especially trends of skill-biased technological change and globalization affecting the demand for low-skilled work and routine jobs. On the other hand, labor market policies and wage-setting institutions, such as minimum wage policies and unionization, determine the extent of wage compression for the given labor supply.

Figure 3 shows the trend in real hourly wage rates for men and women from 1976 to 2011. For men, only the wages of the top 10% of the earnings distribution increased while the real wages of the bottom 50% decreased. For women, in contrast, the wages for all groups increased – resulting in a declining gender wage gap. Yet, the increases were stronger at the top of the distribution. This means that the labor market has become more polarized in the U.S. for both men and women. Since labor earnings account for a large part of incomes, this is an important driver of increasing levels of total income inequality.

Secondly, annual earnings are affected by the individual's decision on how many hours of work per week to supply on the labor market. Patterns of labor supply have considerably changed over the past decades. This is especially true for women, who have substantially increased their educational attainment and are therefore much more attached to the labor

Figure 3 Hourly wage rates in the United States for men and women (1976–2011). Source: March CPS 1976–2011, own calculations. Population aged 21–65 years. Base year 1976 = 100.

Figure 4 Weekly working hours for men and women by age (1980–2010). Source: March CPS, own calculations.

market. In addition, in many countries the increase of female labor force participation, both at the extensive and intensive margins, has been more concentrated at the top of the distribution, which increases the gap in total household earnings between 'rich' and 'poor' couples.

Figure 4 shows the average weekly working hours for men and women of different ages for the years 1980, 1990, 2000, and 2010 in the United States. Several observations can be made. First, prime-aged males always work 40 h per week and more. Secondly, women increased both the average weekly hours as well as their retirement age. Hence, while the pattern of labor supply characteristics of men has remained almost unchanged over the 30-year period, the pattern for women changed remarkably and has become much more similar to that of men.

This is also related to patterns of increasingly assortative mating ("*Doctors marrying doctors, rather than nurses,*" OECD, 2011) and increasing correlation of labor earnings and hours worked among couples. More generally, patterns of household formation and composition have changed tremendously in many Western countries and are related to increasing inequality (see, e.g., Peichl et al., 2012, for an analysis on Germany).

Finally, the number of weeks worked per year reflects fluctuations in employment, which are related to unemployment fluctuations over business cycles. This makes the distribution of gross earnings more unequal; the risk of layoff during an economic downturn is more concentrated at the bottom of the wage distribution. Unemployment rates and earnings inequality are positively correlated.

Figure 5 shows the employment rate (left scale) and average weekly working hours (right scale) for United States men and women over time. While the male employment rate is relatively stable around 80%, total working hours show some variation over the business cycle, the hours worked conditional on being employed are stable and on average above 40 h per week. For women, the number of hours worked conditional on

Figure 5 Employment rates and hours worked by men and women (1976–2011). Source: March CPS 1976–2011, own calculations. Population aged 21–65 years.

employment only marginally increased around the level of 35 h, while total weekly hours increased substantially from 20 to 25 h along with the employment rate from 50% in the mid 1970s to around 70% in recent periods. While long-run trends as well as short-run business cycle fluctuations in labor force participation and employment are of primary concern for labor market policies, they have also important implications for the distribution of labor earnings, since the underlying working force's composition crucially shapes the distribution for given labor market conditions.

Equality of Opportunity

The literature on earnings inequality deals, by definition, with inequalities in (labor market) outcomes. However, theories of distributive justice distinguish ethically acceptable inequalities (e.g., due to differences in effort) from unfair inequalities (e.g., due to endowed characteristics). The concept of equality of opportunity in contrast to equality of outcomes has received considerable attention since the seminal contributions of Roemer (1993, 1998), Van de Gaer (1993) and Fleurbaey (1995). See, e.g., Ramos and Van de Gaer, 2012; Roemer and Trannoy, 2013 for overviews of the equality of opportunity literature. While the traditional notion of equality of outcomes refers to an equal distribution of economic outcomes (e.g., well-being, consumption, or income) across the population, the equality of opportunity theory, in contrast, is interested in the sources of inequality and separates the influences on the outcomes of an individual into circumstances and effort. Circumstances are defined as all factors beyond the sphere of individual control for which society deems individuals should not be held responsible, such as parental education, gender, or ethnic origin. Effort, on the other hand, comprises all actions and choices within individual responsibility for which society holds the individual (partially) accountable, e.g., schooling or labor supply decisions. Inequalities (in income) due to differences in effort are deemed equitable, whereas inequalities due to endowed circumstances are not.

This is related to the literature on wage discrimination (see, e.g., Altonji and Blank, 1999, for an overview). However, a fundamental difference exists between the two fields. Labor economists studying discrimination are usually interested in estimating the direct effect of endowed characteristics (e.g., race, gender) on income and try to separate it from confounding effects due to between-group differences in effort. In contrast, the 'equality of opportunity' literature believes that the confounding indirect effect is also a source of unfair inequalities – i.e., a circumstance itself should not be separated from the direct effect of circumstances on income (see, e.g., the discussion in Roemer, 1998). Therefore, inequality of opportunity is related to wage discrimination, but it is not the same. Unfair income differences in the inequality of opportunity framework can be indeed caused by discrimination, but they could also be due to between-group differences in productivity or preferences. Therefore, the two approaches imply different normative choices about the compensation of the indirect (confounding) effect.

Niehues and Peichl (2014) analyze inequality of opportunity for Germany and the United States. **Figure 6** presents the range for inequality of opportunity shares, i.e., the inequality of opportunity level divided by the level of outcome

Figure 6 Inequality of opportunity shares in outcome inequality. Source: Niehues, J., Peichl, A., 2014. Upper Bounds of Inequality of Opportunity: Theory and Evidence for Germany and the US. Social Choice and Welfare, 43 (1), 73–99. based on SOEP and PSID. The two graphs on the top illustrate inequality of opportunity shares in annual incomes (2009 for Germany, 2007 for the United States); the graphs at the bottom depict inequality of opportunity shares in permanent incomes.

inequality (between group inequality as a fraction of total inequality). The upper (lower) line corresponds to the upper (lower) bound share. Results are presented both for periodical (permanent) incomes in the upper (lower) panel both for the United States and Germany for the full sample, as well as separated by gender for gross (left, darker bar) and net (right, lighter bar) earnings.

The inequality of opportunity shares are significantly higher for Germany than for the United States for annual incomes, which is due to lower absolute levels of outcome inequality along with similar values of inequality of opportunity – which is in line with the findings of Almas (2008). The lower bound shares equal 30% in Germany and 16% in the U.S. – the latter is comparable to previous findings (Pistolesi, 2009). Based on these results, it would be possible to deduce that individual earnings are mainly driven by the individual's effort choices and only to a lesser extent by circumstances. The upper bound estimates, however, suggest that earnings are to a larger extent predetermined by exogenous circumstances. Niehues and Peichl (2014) find upper bounds of inequality of opportunity of around 50% in Germany and 35% in the United States. The differences are statistically significant.

Thus, it seems that there is substantially less inequality of opportunity in the U.S. compared to Germany, i.e., one could conclude that equality of opportunity is higher in the 'land of opportunity.' However, using permanent instead of annual incomes matters for inequality levels, especially in the United States, where inequality of opportunity levels are much higher for permanent incomes (comparable to the findings of Pistolesi, 2009). In Germany, the difference between inequality levels for the two income concepts is much smaller. Therefore, inequality levels (and hence the inequality of opportunity shares) are similar for both income concepts. Hence, the inequality of opportunity shares for permanent incomes are higher in the United States than in Germany.

The lower bound inequality of opportunity shares are substantially smaller when looking at the female and male samples separately. This hints at gender as an important source of inequality of opportunity (due to gender wage gaps and differences in labor force participation). However, the effect is not as strong for the upper bounds based on the unit-effect, as circumstances vary. This indicates that a large share of the inequality in outcomes can be explained by unobserved heterogeneity in individuals.

The differences between gross and net income inequality, i.e., the redistributive effects of the tax benefit systems, are rather similar in Germany and the United States. This might be surprising at a first glance, since European welfare states are usually said to be more redistributive. But in the present case, which focuses on the working age population, this is not the case. The main difference in redistribution between Germany and the United States is due to benefits (especially for the unemployed) and not due to the progressivity of the income tax, which is rather similar in both countries. In our sample, we focus on individuals who are working. They pay taxes and receive almost no benefits – except for child credits, which are comparable in both countries. Hence, the redistributive effects for this subgroup of the population are rather similar both in Germany and the United States.

Conclusions

In this article, we have discussed the topic of earnings inequality and reviewed the existing literature. Inequality is not a bad thing per se. In fact, it is necessary for the functioning of a market economy. Nevertheless, the rapidly growing levels of inequality generate concern for the social stability of Western societies. When talking about inequality, the question of 'inequality of what among whom' arises immediately – and different options have different implications for the results. Hence, results from different studies have to be interpreted with caution. From a normative point of view, an interesting question is whether we should care about inequality in outcomes or rather about inequality of opportunity.

Our descriptive review of some core facts with respect to earnings inequality in the United States, has shown that there is not just one explanation for long-run trends in (increasing) inequality, but rather many. Core labor market conditions as well as changes in the composition of the population, and hence workforce, play an important role. In addition, the tax-benefit system, although not directly affecting gross earnings levels, affects incentives to take up work and also the formation of families and households.

Our discussion has shown that despite the enormous and ever growing literature on inequality, a lot of issues are still left for future research. It would be important to develop a comprehensive model of the household income distribution, incorporating different income sources such as labor earnings, capital, and business income; as well as models for taxes and social benefits that account for demographic factors, such as household formation and composition.

East Africa: Sociocultural Aspects

Abstract

The historical depth, cultural complexity, and social diversity of East Africa, an area encompassing the present nation-states of Tanzania, Kenya, and Uganda, are considered in terms of this region's prominent social forms. These arrangements include, at the most complex level, the precolonial Swahili city-states on the Indian Ocean littoral and the interior kingdoms in and around the great lakes of the region. Other less complex polities are considered by reference to a number of specific and typical ethnic examples. The latter commentary demonstrates the manner in which religion and ritual are employed to generate local social groups and political loyalties as well as the manner in which these arrangements were effected by both the colonial and independence periods. Reference is also drawn to the pervasive cultural themes that characterize the region.

Almost a century of scholarship confirms the historical and cultural complexity of East African societies encompassed by the independent nations of Kenya, Tanzania (including Zanzibar), and Uganda. From the maritime commercial civilizations of the Indian Ocean islands and coast that have traded with the external world for at least two millennia, to the more archaic forms of economic adaptation, including the still extant gathering and hunting societies in the interior, this region displays an exceptional range of social and cultural forms. In addition to Swahili as a regional Bantu language, unique to East Africa, branches of all the other African linguistic families, Nilotic, Cushitic, and Khoisan, are also represented in northern Tanzania.

Prehistory and History

Based on finds at Kobi Fora in Kenya and the Olduvai Gorge in Tanzania, it is now accepted that the earliest hominids emerged in East Africa some 4–6 ma. Although permanent agricultural settlements have existed for at least 10 000 years, historical records on the area extend back only to the first century of the Christian era (Phillipson, 1993). The original Greek manuscript, *Periplus of the Erythrean Sea*, describing the trade routes from Alexandria on the Red Sea in Egypt and then south along the East African coast, mentions Rhapta, a settlement assumed to have existed somewhere on the shoreline of what is now Tanzania. Arabic documents from the eighth century onward are more prolific and exact, indicating the existence of the still occupied trading sites of Lamu in northern Kenya and Kilwa in southern Tanzania. This land of 'Zinj' is described as inhabited by a population that was engaged primarily in a maritime trade in animal skins, horns, and some slaves, but particularly ivory, and that subsisted on agriculture and domesticated herds. Subsequent Arab influence, including Islamization, came to a halt for a time at least with the arrival of the Portuguese in the late fifteenth century and their partial conquest of the then more numerous city-states dotting the littoral. However, these first Europeans were themselves expelled from the area by a resurgent Afro-Arab coalition directed from Oman on the Arabian Peninsula, which in turn failed to establish suzerainty over the entire area.

Subsequent European incursions, primarily British and German, which included penetration of the interior in the latter half of the nineteenth century, hindered the by then more extensive slave trade supporting the offshore, particularly Zanzibari, plantation economies based upon the export of spices. This era culminated in 1885 with the Berlin Treaty, which partitioned all of Africa, excluding Ethiopia, among the European powers, and divided East Africa between Britain and Germany. The results of World War I brought the entire area under British control as a colony, protectorate, or League of Nations mandate until independence in the early 1960s (Oliver and Mathew, 1963).

Social Forms

The existing subsocial formations in recent and contemporary East Africa can be classified in the usual manner as either mercantile or agricultural states, less politically complex agricultural chiefdoms of varying scale, decentralized agricultural and pastoral societies, and the few remaining gathering-hunting groups. However, these categories are heuristic and ideal as most, if not all, of the economies were mixed and interdependent prior to the colonial era. In addition, there was fluidity in economic forms over time as the archaeological data indicate that some gathering-hunting peoples may have resorted to agriculture and then reverted to their previous mode of adaptation on numerous occasions. The same flexibility characterized pastoral peoples. Such adaptive shifts in more recent times have involved simultaneous alterations in ethnic identities that are often labels based primarily upon livelihood. Thus, for example, indigent Maasai who no longer kept cattle were reclassified as *il torrobo* (Maasai for 'the poor' or 'hunters') or Nderobo, while in another instance a whole segment of Maasai who took up agriculture as their primary occupation in the nineteenth century were redefined as Arusha. Thus, in addition to the complexity of social forms, the fluid basis of ethnic identities, often assumed to be fixed 'tribal' isolates, was a constant feature of the region's social history. Although there were and are cultural differences,

in some instances a matter of degree and in others of kind, rigid colonial mentalities and policies often helped to bring into existence these so-called tribes.

City-States and Kingdoms

Prior to the advent of European incursions, complex economic and political entities existed at both extremes of the East African region. The coast, as noted, was intermittently dotted with numerous city-states, while the westernmost interior, some 800 miles away, featured a series of large-scale polities referred to as the interlacustrine Bantu kingdoms due to their clustering around the lakes, such as Victoria and Tanganyika, in the Great Rift Valley. Most notably, these included Baganda, Banyoro, Basoga, and Batoro in contemporary Uganda, as well as Rwanda and Burundi, which eventually fell under Belgian colonial control and reemerged as separate independent nations. These two regional extremes were linked by long-distance commerce, including, by the early nineteenth century, some commerce managed by interior middlemen groups, allowing all concerned to expand and flourish with the exchange of valued trade goods. The Bantu kingdoms were early on the subject of academic scholarship (Beattie, 1971.) However, in part due perhaps to its less romantic and more complex 'untribal' or 'detribalized' condition, the coastal region failed to receive serious scholarly attention until after the colonial era.

Although these ancient city-states, extending 1000 miles along the coast north to Somalia and south to Mozambique, never formed a single political unit, they were linked by a common civilization. In addition to maritime mercantilism, stone cities, marriage alliances, and patrilineal descent, other commonalities included by the eleventh century Islam and a related lifestyle, as well as Swahili as a *lingua franca* (Middleton, 1992). The term 'Swahili' eventually emerged as a complicated and widespread ethnic category referring to peoples on and beyond the coast as the language and Islam spread throughout East Africa before and after the colonial period. The word 'Swahili' itself is derived from the Arabic *sahel*, meaning 'coast.' The language has a modicum of loan words from this source, but otherwise it is Bantu in all of its essential grammatical features. As it was adopted as a first or second language by others in the region, many also identified themselves as an mswahili or as waswahili (a Swahili person or people, respectively), which implied not only language usage but also a form of modernization involving the adoption of Islam or even Christianity, migration to other areas of the country for one's livelihood, and a modified Arab or European lifestyle, including forms of dress and architecture. Among themselves in the towns and cities they inhabit, the Waswahili may also admit to another ethnic affiliation, reaffirming the plasticity of this sort of identification (Arens, 1976).

The agricultural bases of the interior states situated in fertile highland areas with the banana (originally from Indonesia) as a staple may have been the historical outcome of an incursion of northern cattle-keeping peoples into an area inhabited for at least 1000 years by Bantu-speaking agriculturalists. The high population densities, in the case of Baganda close to 2 million people, and social complexity resulted in what has been described as semifeudal states involving unequal control over resources, including land and cattle; concomitant social stratification (though no caste system); and, in most instances, a series of patron–client relationships spanning economic and political divides. These kingdoms, which shared a host of cultural similarities in addition to economic and social ones, competed with each other for more extensive control over the region. At the apex of the highly centralized political systems stood a king advised by a prime minister and other councilors, who appointed chiefs over large districts who in turn delegated authority to headmen in villages. Although often popularly viewed as a despot, it is unlikely that the king could have achieved this level of power and authority until the introduction of firearms in the early nineteenth century via trade from the coast. The stability of the entire political-economic system was further solidified with colonialism and its application of indirect rule that permitted little if any challenges to established authority or radical changes to the system. Although these were not the only centralized political systems in East Africa, as others of varying degrees in other highland areas existed beyond the coast, including the Shambaa and Chagga of Tanzania (Feierman, 1990), the vast majority of the population in the less watered lowland savannas and woodlands of the region, shared with pastoral peoples, were organized into smaller political units.

Agriculturalists and Pastoralists

Among the agriculturalists, the traditional crops were millet, sorghum, and maize. In the more abundantly watered areas, rice and bananas were also cultivated. Reference here should also be made to the now abandoned stone city of Engaruka in the northern part of the Great Rift Valley in Tanzania. This stone settlement based on irrigation agriculture and with at least 5000 people was abandoned some 300 years ago for no apparent reason, though the event does correspond to the appearance of the Maasai in the area at that time (Robertshaw, 1986).

Cattle, which play such a significant cultural role in the entire area, including among agriculturalists, and smaller livestock such as sheep and goats were also maintained whenever and wherever possible. Politically, this is the 'tribes without rulers' region as termed by one of the classic anthropological volumes of the colonial period and the 'golden age' of East African ethnography (Middleton and Tait, 1958). This vision of much of the social landscape was influenced in no small part by the prior research of E.E. Evans-Pritchard among the acephalous pastoral Nuer of the neighboring South Sudan (Evans-Pritchard, 1940). In light of the range and variability of societies in East Africa proper, they are best represented by a limited number of examples that also reflect the interests of the ethnographers at different points in the history of East African scholarship.

The quarter of a million Sudanic-speaking agricultural Lugbara, who live along the Nile–Congo divide on both sides of the Uganda–Congo border, are characteristic in that they had no political offices until chiefs and subchiefs were appointed by the colonial authorities. This lack of a formal political system was somewhat unusual in light of their relatively high population density, which exceeded 100 people per square

kilometer in some areas in the early twentieth century, but is explicable in light of the absence of nucleated settlements. The basic social unit was the homestead of various sizes composed of patrilineally related kin. This family cluster recognized the authority of a senior male elder with ritual significance due to his control over shrines dedicated to the lineage ancestors. Thus, at its core this social group had both a descent and a related religious ideology.

The Lugbara themselves conceive of their social structure in terms of clans originally historically associated with specific territories despite the dispersal of their members over time. As such, principles of descent provided an ideological rather than actual form of social organization, as is the case for many other East African peoples. These recognized territories may have a 'rainmaker' with ritual authority in certain matters but, as indicated, no formal leader. Order was maintained by compromise and conciliation among the resident elders. Disputes among members of different territorial groups were difficult to mediate and as such could result in violence and a state of feud. However, since clan kin were dispersed among the various Lugbara, tribal units and marriages were also effected across these lines, resulting in affinal relationships; thus violence was not entered into easily, especially among contiguous territories. More distant Lugbara tribal sections presented less opportunity for conflict, and if a state of feud did exist, it was difficult to act upon as the result of spatial separation. Thus, there was a political order, despite anarchy in the technical sense of the term, among these people, who recognized a common moral code supported by the ritual authority of elders and ancestors (Middleton and Tait, 1958).

The manner in which social order or stability was maintained among a people lacking a well-defined political system was one of the driving research concerns during the colonial era, while change became a principal interest of postcolonial scholarship. This shift in orientation is exemplified by the situation and description of the Iteso, Nilotic-speaking sedentary cultivators residing in this instance on both sides of the Kenya–Uganda border. By the time of their analysis, the Iteso were almost all Christians, and their expansionist tendencies, as well as the former political system that had permitted this process, had been radically altered by the often violent imposition of colonialism. According to historical reconstruction, prior to European intervention the Iteso were organized into a number of territorial sections under the leadership of a single individual or 'war leader.' These units were broken into a number of subsections that tended to correspond with the residence of patrilineally related males who also recognized a local leader for political and ritual purposes. These locations undertook common defense, the peaceful settlement of disputes, and collective religious activity. Typical of Nilotic speakers, the territories were cross-cut by an age grade system including a warrior class that had facilitated Iteso incursions into the lands of other ethnic groups. During the colonial period, appointed chiefs replaced the former leaders and the territorial units dissolved, as neither expansion nor defense was a relevant concern. These aggregations were replaced by diffuse neighborhoods of a smaller social scale composed of cooperating but individual households now engaged in the cash economy. The resulting process generated a typical East African society brought into being by the colonial presence. Similar ethnic consolidation and consciousness among the more numerous Kikuyu and Luo peoples of Kenya emergent during the colonial era had significant impacts on postcolonial politics (Karp, 1978).

The primarily pastoral Nilotic-speaking peoples inhabiting a grassland expanse in both arms of the vast Rift Valley in eastern Uganda, western Kenya, and north-central Tanzania provide a striking alternative to agricultural societies in more than economic fashion as many of the representatives of this language family have preserved their traditional cultural system to this day. Included in this category are the Jie, Karimojong, and Turkana of Uganda; the Kipsigis, Nandi, and Samburu of Kenya; and the Barabaig of Tanzania. However, the quarter of a million Maa speakers or Maasai who have occupied the central plains of both Kenya and Tanzania for the past 400 years are best known for the persistence of their traditional ways despite impositions placed on their lifestyle by both the colonial and independence-era regimes (Spear and Waller, 1993).

The enormous expanse of Maasailand is divided into numerous large and politically autonomous named territorial sections that, in some instances, cover thousands of square kilometers and include tens of thousands of individuals. Within these sections, social order is maintained at the local level by male elders with either ritual or judicial authority derived from membership in a particular clan, age grade, or local community of kin. Although patrilineal in terms of descent principles, kinship ties of various types are a significant factor only at a settlement composed of a number of usually polygynous households that herd their animals together under the direction of a senior male. The most striking feature of the social system is the age grade system bisecting the entire expanse of Maasailand, which includes the Moran, who were formerly a warrior class of young men but are now primarily responsible for cattle herding (Hodgson, 2011).

For the Maasai, cattle are not only the basic foodstuff in the form of milk, meat, and blood but also the most important cultural idiom. The animals are valued in and of themselves as esthetic items, the object of admiration, discussion, song, and dance, but they also mark both existing social relations through their exchange, and the passage of time through inheritance. They are circulated as bride wealth and blood wealth (the latter in compensation for violence), and they are loaned out to establish herding partnerships over wide areas. Finally, these animals are the primary means for communicating with the supernatural world as sacrificial offerings to the creator in religious ceremonies (Århem, 1985). Thus, this single item links humans both to each other and to their deity in a manner that is unavailable to cultivators. In more practical economic terms, the ability of the Maasai and other pastoralists to sell some animals for cash to meet the demands of the state in the form of taxation has permitted them to avoid social integration and in doing so conserve existing cultural patterns.

Foragers

Scattered among the pastoralists and agriculturalists in both forests and plains are pockets of hunters and gatherers, such as the Mbuti Pygmies of western Uganda and the Congo. Other foraging groups, though physically distinct from the Mbuti,

include the Okiek of Kenya, the Ik of Uganda, and the Sandawe and Hadza of Tanzania. The forest-dwelling Mbuti and related populations generally are considered to be descendants of the first residents of this and other parts of Africa who have adopted the languages of their later arriving and now Bantu neighbors, while the Okiek and Ik speak the related Nilotic languages of their pastoral neighbors. However, Sandawe and Hadza bear some phonetic similarities to the tongues of hunters and gatherers in southern Africa. Despite the traditional academic classification on the basis of foraging, there are also variations among these peoples, including the tendency to mix this adaptive strategy with agriculture and herding when feasible. Thus, a portion of the few hundred Hadza residing in a desolate region of northern Tanzania that was unsuitable until recently for either agriculture or herding are interesting in that they maintained a foraging lifestyle in pure form, as well as a significant degree of economic independence, from surrounding groups and the state.

Although seemingly inhospitable to others, the Hadza territory of over 1000 square miles, open to any member of the group as there are no recognized territories, is replete with natural resources harvested on a nomadic and individualistic basis. Although the area is heavily populated with game, the Hadza rely mainly on wild vegetable matter for food in the form of roots, berries, and fruit gathered daily by both males and females, the latter with their small children. These nutrients usually are consumed immediately rather than being collected for later distribution. Traditional bow-and-arrow hunting, however, is exclusively a male activity. If the kill is small, it is also eaten on the spot, while some of the remains of a larger animal may be either transported back to camp or simply abandoned. Thus, there is almost complete economic independence even among the Hadza themselves. As such, it would be misleading to characterize their local aggregations as bands in the sense of groups recognizing a common territory or cooperative bonds. Beyond the nuclear family, based on relatively unstable monogamous unions, the larger and only unit is a camp, occupied for no more than a few weeks, and on average by a dozen or more adults. This aggregation does not have a recognized leader, nor does it form a stable unit, as some members join or depart on a constant basis. At other times, it may split off into independent units or merge with other camps for a period of time. This organizational fluidity of foraging societies is perhaps their characteristic feature in both East Africa and other parts of the world (Ingold et al., 1988).

Cultural Concerns

This overview of East Africa in terms of economic, political, and social forms in no way suggests a paucity of equally, if not more, complex cultural systems including beliefs, values, myth, history, and literature both oral and written. These integrated systems of thought, often shared over a wide area, even in terms of particulars, defy simple categorization into a number of ideal types. In general, the peoples of this region, regardless of their form of economic adaptation, must be considered highly spiritual, whether in terms of their adherence to the local religions or the world religions that have supplanted them. In turn, these cosmologies have been transformed by local beliefs and practices. As in other parts of the world, the traditional ideological systems took a great interest in notions of good and evil and thus acceptable standards of interpersonal morality guarded by the living as elders and/or the deceased as concerned ancestors. The 'problem of evil' in society was often represented (by agriculturalists in particular) as a matter of witchcraft or sorcery that was resolved by recourse to diviners who could identify the culprit in order to restore a harmonious social order through confession and reconciliation.

As indigenous philosophies, these systems of thought also reflected on the meaning and passage of life and the significance of death, occasions usually marked by elaborate ritual gatherings and activity. Communication with their creator, most often viewed as a more distant and less knowable figure than in world religions, traditionally was maintained through prayer and sacrifice. Indeed, as this review of primarily social forms suggests, it was and is often best to view many East African peoples at the local level and in the most meaningful sense as composed of ritual communities concerned with the spiritual and social welfare of their members (Karp and Bird, 1980).

Globalization and Modernity

The effects of globalization and resulting forms of indigenous modernities have been a mixed blessing for the region. Tanzanian has undergone significant reorganization with economic liberalization but remains politically stable and peaceful with the emergence of a multiparty system relatively free of ethnic, regional, and/or religious pressures. Kenya, however, has at times succumbed to these divisive forces with a degree of internal political violence with ethnic overtones. It also confronts global conflicts as violent local disturbances on its borders with Somalia and the recently formed South Sudan. Uganda has yet to resolve some breakaway rebellions and its relations to neighboring states.

The entire region, but particularly the Swahili coast of Tanzania and Kenya, has had to adjust to the impact of international leisure tourism, importing with it European cultural patterns often at odds with a more conservative Islamic ethic. The results have been local conflicts between the generations and in some instances confrontations between the local community and the state (Caplan and Topan, 2004).

East Asian Legal Traditions

Abstract

Most East Asian legal traditions were heavily influenced by Chinese thought and statecraft, which can be traced back at least 3000 years. Confucianism, which made familial duties a central feature of all social obligations, had a formative impact on both the Chinese and the Korean legal orders. Japan was also heavily influenced by the Chinese legal system, but was more selective in its adoption of those models, because of the fragmented nature of the Japanese political order. Beginning in the late nineteenth century, East Asia came under heavy Western influence and all legal systems were ultimately reformed on Western models, leaving few formal traces of the previous legal order.

With a recorded history of more than 3000 years, the legal orders in China proper have exercised a major influence not only on its neighbors, especially Korea, Vietnam, Ryūkyū, and Japan, but also on a number of 'conquest dynasties' that ruled parts of traditional Chinese territories or controlled areas contiguous to China proper. Practically everything we know about the early states that existed in proximity to the Chinese dynasties has been handed down to us through the medium of classical Chinese, and East Asian rulers took the ideal of the Han (206 BC–AD 220) and Tang (618–907) dynasties at the height of their power as the purest expression of an idealized Confucian order. Therefore, any inquiry into East Asian legal traditions has to begin with a discussion of the legal orders that developed in China proper from the first millennium BCE. At the same time, we have to be cognizant of the fact that the uniformity of the written Chinese language, which was the preferred idiom of Chinese dynasties and many non-Chinese states, often masks the realities of societies that were regionally, ethnically, and socially diverse, and subject to significant change over time. Consequently, no claims of a continuous and unbroken East Asian legal tradition harking back to Chinese antiquity should be taken at face value.

The Great Tradition

Very little is known about the legal order in preimperial China, but fragments of laws from the western Zhou dynasty (1050–771 BCE) have survived in bronze inscriptions and historical chronicles. One of the earliest historical records on the early Chinese legal order is found in the chapter 'The Punishments of Lü' in the canonical historical work *Book of Documents* (*Shàngshū*), which outlined some early laws and the classical form of the 'Five Punishments' (*wǔ xing*). It is unclear whether the original five punishments were ever practiced, but in their classical iteration, they included 'tattooing of the face' (*mò*), 'cutting off the nose' (*yì*), 'cutting off the feet' (*yuè*), 'castration' (*gōng*), and 'decapitation' (*dàpì*). It is not clear if any single code existed during the Zhou dynasty, but there is ample evidence that laws were recorded on bronzes during the Chinese antiquity. At a very early stage, Chinese thinkers seem to have regarded legal action, litigation, and punishment as signs of failure on the part of the sovereign's ability to exercise a moral influence on its subjects to abstain from criminal and other asocial acts. Thus, it is not surprising that the introduction of penal law is attributed to the non-Chinese and according to the *Book of Documents*, the five punishments were handed down from non-Chinese peoples, such as the Miao People in what is today southwest China (Creel, 1970).

The eastern Zhou dynasty (770–256 BC) witnessed the weakening of central royal authority and the relative strengthening of the Zhou vassals, who emerged on ambitious projects of state building and availed themselves of the advice from a new class of literati. During the Spring and Autumn (770–476 BC) and Warring States (475–403 BCE) periods, a number of contending schools of statecraft emerged, many of which claimed to have answers on how to best use law and punishment to create strong and prosperous states. The two most successful schools were the Confucian and Legalist schools of thought. Very much in line with earlier trends in Chinese thought, the Confucian school argued that the family was a microcosm of the state and that a just ruler should govern by providing good example to his subjects by maintaining the Confucian family system and rituals, which were supposedly perfected by the sage kings of the Xia, Shang, and Zhou dynasties. Confucians saw laws and punishments only as a last resort and warned that excessive use of punishments would only make people into fawners who did not internalize the positive norms of the Confucian order:

> Guide them by edicts, keep them in line with punishments, and the common people will stay out of trouble but will have no sense of shame. Guide them by virtue, keep them in line with the rites, and they will, besides having a sense shame, reform themselves.
> Confucius, 1979: 63

Confucians also assumed that common people would harbor a higher sense of loyalty toward their family than to the state, and Confucius explicitly approved of family members covering up each others' crimes (Confucius, 1979: 121).

The Legalist school did not disfavor familial duties per se, but it argued that a strong and prosperous kingdom could only be maintained if the ruler applied strict and predictable rewards and punishments, which would produce politically obedient and economically productive subjects. In contrast to the Confucians, who idealized the early feudal Zhou state and denounced vassals who proclaimed themselves kings as

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86139-5

usurpers, the Legalists wanted to establish a centralized and militarized state that imposed heavy obligations on its subjects. They saw law as an extension of administrative power and regarded rewards (*shǎng*) and strict punishments (*fá*) as central tools of a 'behavioral science' that would produce law-abiding and productive subjects who would render loyal service to the state (Schwartz, 1985). Indeed, the Chinese term for legalist (*fǎjiā*) can be translated as both the 'school of law' and the 'school of methods.' The legalists also advocated that all laws should be equally applied to all subjects of the state, regardless of social status, with the notable exception of the sovereign himself. The King of Qin, Ying Zheng (260–10 BC), was one of the most prominent patrons of the legalist schools and when he established himself as hegemon of China proper and the First Emperor of Qin in 220 BC, the Legalist school scored an early victory against the Confucians and participated in the building of a strong state where centrally controlled counties and prefectures replaced the old territorial states of the Zhou vassals.

Very few fragments of Qin Law have survived to this day and the Qin dynasty did not survive the death of the first emperor by many years; when Liu Bang (256/247–195 BC) established the Han dynasty in 206 BC, he not only preserved the centralized state structure of the previous dynasty and many of its legal institutions, but also set out to restore the status of Confucianism as the central doctrine of the state. One product of this endeavor was what the legal historian Chü T'ung-tsu dubbed the 'Confucianization of law,' that is, the ambition to enforce Confucian norms and family hierarchies through penal means, an idea that probably would not have appealed to the founders of the Confucian school, yet this set the pattern for most subsequent imperial dynasties (Ch'ü, 1965; Goldin, 2012). The Han Code itself has only survived in fragments and scholars have had to resort to careful reconstruction in order to provide a full picture (Hulsewé, 1955). After the fall of the Han dynasty in 220 AD, China was divided into a number of competing dynasties that contended for hegemony over the central plains and only periodically unified under a centralized state. In order to bolster their claim to legitimacy, the contending states maintained many of the institutions that harkened back to the Han dynasties, but this often covered up political realities that failed to live up to the meritocratic and Confucian ethos of the Han Dynasty (Hucker, 1985: 17).

China and East Asian Legal Orders during the Middle Period

The short-lived Sui dynasty (581–618) unified China and promulgated a penal code shortly after its ascension to supremacy, but the original text of the code disappeared when the dynasty crumbled and is no longer extant. However, most of the Code survived, as the subsequent Tang dynasty (618–907) based its 653 penal code on the Sui Code. The Tang Code, which consisted of 501 articles and was divided into 12 thematic sections, is the earliest legal code that has survived in its entirety. Practically all laws in the Tang Code were of a penal character and there was no separate code regulating private relations. The law was hierarchic in nature and the much-vaunted 'Confucianization of law' was manifested in the fact that criminals, when found guilty, were sentenced in accordance with their status in the Confucian family system, defined by the 'Five mourning degrees' (*wǔ fú*). Another expression of both Confucian hierarchies and the aristocratic nature of Tang society was the 'Eight deliberations' (*bā yì*), which provided for various forms of special treatment for status groups, such as the imperial house and virtuous officials (Johnson, 1979).

In the Tang Code, the five punishments were redefined as 'caning with light stick' (*chī*), 'caning with heavy stick' (*zhàng*), 'penal servitude' (*tú*), 'life exile' (*liú*), 'military exile' (*chōngjūn*), and 'capital punishment' (*sǐ*). Capital punishment was divided into two categories, strangulation (*jiǎo*) and decapitation (*zhǎn*), where the former was regarded as the more lenient form of punishment as the delinquent would be spared the humiliation of dismemberment, which violated Confucian concepts of filial piety. This schematic division of punishments, which would remain in force for most of China's imperial history, was subject to different modifications and commutations. For instance, some physical punishments were subject to certain kinds of reductions, and certain groups, such as minors and senior citizens, were able to substitute corporal punishment with monetary redemption. Furthermore, criminals who voluntarily submitted to the authorities (*zì shǒu*) were punished more leniently as long as their crimes did not belong to the 'ten abominations' (*shí'è*), a series of crimes of a certain heinous nature, such as sedition, rebellion, or parricide. The idea that one should receive a more lenient punishment as a result of voluntary confession is still prevalent in many East Asian countries (Ricket, 1971).

A core feature of Chinese legal procedure was the centrality of confessions and other types of written evidence, as opposed to other forms of technical evidence. Although the Chinese legal order had developed a relatively sophisticated forensic science, which purported to be able to identify different causes of death (Song and McKnight, 1981), the central piece of any criminal case was a confession of guilt on the part of the accused, who in principle could not be convicted without his own admission of culpability. Consequently, the Chinese legal system permitted a certain use of torture and other means of coercion in order to obtain correct confessions. At the same time, the risk of extracting false confessions under duress was recognized and magistrates who abused torture and punished innocent people were subject to disciplinary and criminal sanctions.

Intimately tied to the importance of written evidence was an 'appellate system' of justice, which took shape during the Tang dynasty, according to which severe criminal sentences had to be reviewed and sanctioned by higher instances in the bureaucracy, sometimes by the emperor himself, in order to have legal force (Bodde and Morris, 1967). Another characteristic of the Sui-Tang bureaucracy was the introduction of a rigorous examination system, which selected aspiring officials on the basis of their proficiency in the Confucian classics, and the rule of avoidance, which laid down that local officials could not serve in their native province. Both of these measures were designed to provide an imperial check on the great aristocratic families, which were centered on the dynastic capital of Chang'an (present Xi'an), and were in all likelihood

imperfectly implemented, but they did provide the basis of an idealized meritocratic ideology, which would gain in strength and influence in subsequent dynasties. The Sui-Tang legal order had a formative impact on the legal orders of many of China's neighbors. For instance, the Taika reforms of 645 and the introduction of the Ritsuryō system in 701 were two programs that set out to centralize imperial power according to Chinese patterns of law and governance; however, the weakening of the central authority in Japan led to the emergence of a feudal order by the twelfth century, under which the imperial court in Kyoto was largely incapable of asserting its political and legal influence over local territorial warlords, who had taken power in the provinces. This state of affairs paved the way for a legal order with a large degree of local diversity.

The Tang dynasty reached its apogee in the mid-ninth century and finally collapsed in 907, but its legal system and institutions enjoyed a high stature, not only in China proper, but also in East Asia, and both Japan and Korea adopted the Tang Code as a model, although both polities retained many native institutions as well. In China itself, the Tang Code became the basis for most subsequent penal codes, with the exception of the unapologetically alien Yuan Dynasty (1271–1368). The Song dynasty (960–1279) inherited many of the codes and legal institutions of the Tang state, but the coherence of the legal system was encumbered by a proliferation of different types of laws, such as the Code itself, edicts, law compilations, and precedents. From the Song dynasty, we also have the first extant case collections, which have provided scholars with valuable insights on how the legal order operated in practice (McKnight and Liu, 1999). The transition from the Tang to the Song dynasty is notable as it marks the final demise of the great aristocratic families, which had dominated politics and court life during the period of division, and the emergence of local elites, which competed for government service in the examination system.

The short-lived Yuan dynasty represents one the sharpest ruptures in Chinese legal history and the relative paucity of extant primary sources has made it difficult to study the legal system of the dynasty in detail. While the Mongol rulers did rely on some Chinese institutions and issued administrative laws on a Chinese pattern, they were not beholden to the Confucian tradition and chose not to adopt a single written Chinese code to administer their empire, but relied on different sources of law such as imperial edicts and Mongol customary law. The Mongols practiced legal pluralism rather aggressively and divided the population in their Chinese empire into four different categories, namely, Mongols, Central Asians (*sèmù rén*), Northern Chinese, and Southern Chinese, in descending order of status. Each group was subject to different laws and jurisdictions, and conflicts between different groups were resolved through joint conferences between officials holding jurisdiction (Ch'en, 1979).

The Late Imperial Age

The establishment of the Ming Dynasty in 1368 represented a restoration of Han Chinese rule over the territories of China proper and the founder of the dynasty, Zhu Yuanzhang, created legal and political institutions modeled on the Tang Dynasty to justify his regime as a restoration of a Confucian form of government. The central piece of this legal order was the Ming Code, which was a reorganized version of the Tang Code and reached its final form in 1397. Just like its precursors, The Ming Code (*Dà Míng lǜ*) was a criminal code and the statutes (*lǜ*) were divided into six major sections that corresponded to the Six Boards (*Liù bù*) in the central government: personnel, family and revenue, rituals, military affairs, and criminal affairs. In keeping with the tendency to enshrine Confucian ethics through penal sanction, Ming legislators took filial piety (*xiào*) and other Confucian family very seriously and they made a point in abolishing some Mongol practices that were repugnant to Orthodox Confucians, such as levirate (compulsory marriage of a widow to a brother of her deceased husband), which violated the Confucian family system. Violent crimes were seen as more severe the closer the criminal was related to the victim and the more junior he or she was compared to the victim. The opposite principle was at work when it came to property crimes (Jiang, 2005: lxxii-lxxiii). Yet at the same time, the Ming penal order preserved certain elements of earlier legal orders, such as the notorious punishment of 'slow slicing' or 'death by a thousand cuts' (*língchí*), which was an unorthodox punishment of unclear origins used for crimes against the state and grave transgressions against the family (Brook et al., 2008).

Under Ming, the Chinese legal order reached new heights of centralization and during the dynasty the principle that all capital cases should have imperial sanction was established. In contrast to earlier dynasties such as the Song, the Ming Dynasty used law as an educational tool; trials were in principle open to the public and the Ming Code and other legal manuals were available for purchase to those who could afford them. Crime fiction also became a distinct genre during the Ming Dynasty, which also disseminated knowledge about the legal system among the reading public (Farmer, 1995)

The Ming Code exercised considerable influence on the legal systems of China's neighboring countries, most notably Korea. The Chosŏn dynasty (1392–1910) used the Ming Code as its basic criminal code until the late nineteenth century and built its own legal order on the basis of the Ming system of government. The Chosŏn kings also introduced important modifications to Ming laws and institutions so as to accommodate the rather stratified Korean social order, where slavery and other forms of bondage were more prevalent than in China and where the hereditary *yangban* class exercised a much stronger influence than the Chinese scholar-gentry ever was capable of attaining (Hahm, 1967).

In 1644, the Ming dynasty fell to domestic rebellion and the Tungus Manchu people conquered China proper and established their Qing dynasty (1636–1912) in Beijing, proceeding to build a vast polyethnic empire that reached its apogee in the late eighteenth century. Because of the regional, social, and ethnic diversity of the Qing Empire, the Manchu emperors maintained a plural legal order, where different ethnic groups often were subject to different laws and jurisdictions. In the provinces that had been conquered from the Ming dynasty, the Manchus preserved and developed the Ming legal and political system; the legal system in Manchuria was modeled on the Ming system of law with important modifications, but was administered separately from China

proper. In Inner and Outer Mongolia, the Qing court applied a separate legal code for Mongols, which was a fusion of Mongol and Chinese legal norms, and in Xinjiang a mixture of Chinese law and Moslem law prevailed, administered jointly by Manchu officials and local headmen. The vast Tibetan territories of the Qing Empire, which constituted roughly a quarter of its area, were mostly subject to a theocratic legal system strongly infused with Buddhist thought and practices, which was only partially under Chinese influences. Finally, the ruling caste of the Manchus and other allied groups were technically subject to the Qing Code, but were enrolled in the Eight Banners (*Bā qí*), a social and military organization that constituted largely its own legal sphere, centered on Beijing and the banner garrison that had been stationed at strategic locations in the empire. Consequently, the Qing Empire was in many ways a continuation of previous 'conquest dynasties' that had ruled a part or the whole of China, such as the Liao (907–1125), Jin (1115–1234), and Yuan Empires. The full complexity of these plural legal orders has yet to be comprehensively explored by historians.

The Qing Code (*Dà Qīng lǜlì*), which was first adopted in 1646 and reached its mature form in 1740, is often incorrectly presented as a mere extension of the Ming Code. While it is true that the first version of the Qing Code was largely identical to its Ming counterpart, the Qing government supplemented and modified the Ming criminal statutes with numerous substatutes (*lì*), which took precedence over statutes whenever there was a conflict between the two forms of law. Many of these substatutes emerged from imperial edicts and rulings in case law, which produced the need to modify the code. These constant revisions of the law spawned a huge commentarial literature as well as legal handbooks, which were produced to assist local magistrates in reaching correct verdicts and were available to anyone who could read. During the Qing dynasty, as in previous dynasties, there was no division of power within the legal process and no separate legal profession emerged as a result of the expansion of the legal system. Quite the contrary, it was illegal for commoners to advise strangers in legal matters, as this conflicted with the Confucian ideal of the legal system being the last resort to resolve conflicts.

The Qing dynasty is the only imperial Chinese regime that has left behind a large corpus of archival material, and following the opening of archives in mainland China and in Taiwan in the 1980s and 1990s, historians have been able to study the operation of the legal system in detail, from the magistrates' chancelleries in the roughly 1300 counties in China proper, to the ministries in the central government. We now know that ordinary Chinese were far more likely to resort to legal action than was previously thought and scholars have also found that magistrates were often called upon to adjudicate disputes of a private and commercial nature (Huang, 1996), but it remains a moot point whether the Qing legal order produced any functional counterpart to the system of private law in early modern Europe (Bourgon, 2002). Suffice it to say that the concept of 'law' in Qing China remained largely a penal concept and the dynasty did not promulgate any legal code to regulate private and commercial disputes until the early twentieth century.

Unlike the Korean legal order, which had been under heavy Chinese influence for millennia and had copied Chinese legal codes almost verbatim, Japan was never fully part of the Chinese tributary order and Japanese lawmakers were much freer to choose what aspects of Chinese legal culture they wanted to adopt as their own. Furthermore, Confucianism did not exercise the same ideological hegemony in Japan as it did in China and Korea, but had to contend with other schools of thought such as Buddhism and Shintō, both of which exercised a strong counterweight to any efforts to Confucianize Japan. Following the collapse of central imperial authority in Japan in the twelfth century and the emergence of a feudal political system centered on the warrior aristocracy, the legal system in Japan became even more regionally diverse and fragmented than on the Asian mainland.

When the Tokugawa Shogunate established its hegemony over the Japanese archipelago in the early seventeenth century, the new rulers created a legal and political order where local territorial lords were integrated into what has been called a system of 'centralized feudalism' and the emperor in Kyoto retained his sacral and ritual authority under strict shogunal supervision. A central feature of the Tokugawa legal system was the regulation of the four major status groups – samurai, peasants, artisans, and merchants – which were subject to different laws and jurisdictions are were not encouraged to interact on a daily level so as to prevent cross-jurisdictional crimes from occurring. The status system was further complicated by the fact that every domain maintained its own version of the status system and legal cases involving more than one status group and more than one jurisdiction could lead to intricate legal cases, where shogunal officials from the shogunate were called upon to formulate a verdict.

The dominant Tokugawa house, which directly controlled more than 40% of the four main islands of Japan, exercised a strong regulatory and normative influence on the domanial lords, but it refrained from interfering in their internal autonomy or legal affairs. The Tokugawa legal system relied on a number of different sources of laws, such as the ancient Ritsuryō system, shogunal edicts, case precedents, and legal reasoning (Henderson, 1965). The shogunate did not elaborate a single legal code for Japan, but promulgated a series of codes that regulated the affairs of the imperial court and the court nobility, the territorial lords, and a collection of verdicts in lawsuits. China remained a model when it came to the penal system, where banishment, corporeal punishment, and different forms of capital punishments formed the backbone of the Japanese penal system, supplemented by indigenous penal practices and imported ones, such as crucifixion. Just like in other states on the East Asian mainland, torture and other forms of physical pressures were used to obtain evidence and great emphasis was placed on confessions of guilt on the part of the accused. The Tokugawa state sponsored neo-Confucianism as a state ideology with increasing zeal and as part of these endeavors, Japanese Sinologists were employed to draft new legal codes based on the Tang and Ming Codes, efforts that were emulated in many feudal domains, but none of these efforts led to any wholesale reform of the Japanese legal order. Furthermore, in contrast to the contemporary Qing dynasty, laws were not made public and trials were usually held in camera, which meant that commoners could only learn about the law indirectly through publicly posted verdicts (*kōsatsu*).

Modern Transformations

Following the arrival of modern gunboats to the Western Pacific and the resulting conclusion of commercial treaties in the mid-nineteenth century, East Asian legal traditions were challenged for the first time by Western legal norms, in both their continental European and Anglo-Saxon varieties. Unwilling to submit themselves to what they regarded as barbarous and uncivilized systems of justice, the Western treaty powers forced their reluctant hosts to accept the practice of extraterritoriality, which put most foreigners outside of local laws and jurisdiction. The East Asian polities did not initially contest extraterritoriality in a systematic way, as many of them already possessed multiple legal codes and complex institutions for the adjudication of disputes between different social and ethnic groups. But when East Asian states embarked on nation-building projects that aspired to build militarily and economically strong states with an actively participating citizenry, extraterritoriality was increasingly perceived as an obstacle to those projects.

The first country to challenge the new framework of trade and diplomacy, often called the 'treaty port system,' was Japan, where a group of domains toppled the shogunate in 1867–68 and established the Meiji Emperor as the figurehead of a centralized nation state in the new capital of Tokyo. Realizing that the Western imperial powers would not agree to any revision of the commercial treaties or to the abolition of extraterritoriality without corresponding changes in the Japanese legal system, the oligarchs of the Meiji state embarked on an ambitious program to reform their legal and penal system to conform to contemporary Western standards. While early Japanese legal reformers initially drew on early attempts to reform the legal system along Chinese lines, these efforts were soon cast aside in favor of a wholesale legal and institutional reform, which left discernable few traces of the old Tokugawa legal order. Even the legal language changed beyond recognition, where Chinese characters formed compounds that were used to convey new legal concepts borrowed from the West. Reforming the criminal code, the judiciary, and the penal system did not present an insurmountable obstacle to Japanese legal reformers, but the promulgation of a civil code on a continental European model did meet considerable resistance from conservative elements within the Japanese government, who feared that continental European civil codes would undermine the 'national polity' (*kokutai*) of Japan. By the mid-1890s, the complete overhaul of the Japanese legal system was accomplished and, starting with Britain, most Western nations agreed to renegotiate the 'unequal treaties' and abolish extraterritoriality.

Qing China and Chosŏn Korea proved to be more resistant to foreign incursions into their legal and political orders. Although China was soundly defeated in a number of armed confrontations with the West, the first concerted attempt to reform the legal and political order did not take place until after the defeat in the First Sino-Japanese war 1894–95 and the Boxer War 1900, when the Qing government set out to abolish the old civil service, reform the administration of justice, abolish torture and physical punishments, and introduce criminal, civil, commercial, and administrative codes on Western and Japanese models. Although these reforms seemed promising, the Qing dynasty fell in 1911 and subsequent legal reforms had to be undertaken in a less stable political order that was plagued by civil war and foreign aggression. By the time the Republic of China had introduced a draft constitution and Six Codes, China was invaded by Japan in 1937 and the abolition of extraterritoriality in 1943 was more a product of great power rivalry than of legal reform. Korea was even less fortunate than China in that it soon fell prey to Japanese colonization and was annexed into the Empire of Japan in 1910, which meant that Korea's legal modernization took place under colonial conditions (Kim, 2012).

Following the end of World War Two and decolonization, East Asian nations went their separate paths, depending on which camp they had joined in the Cold War. The People's Republic of China and North Korea adopted Soviet-inspired legal institutions and codes, whereas Japan, Taiwan, and South Korea continued to draw on European and American models for legal reform. Economic reform in Mainland China after 1978 led to a second wave of legal reform, where the Beijing regime embarked on ambitious attempts at codification that are still underway. Today, very few formal traces of the East Asian legal tradition remain in either of these polities and it remains a moot point to what extent Confucianism, for instance, is still a relevant source of legal norms in East Asia. Yet recent advances in East Asian legal history have reopened several important questions on what constitutes a contemporary East Asian legal tradition and the economic rise of East Asia in general and China in particular will ensure that this discussion will be of perennial significance.

East Asian Studies: Culture

Abstract

The studies of the cultures of China, Taiwan, Korea, and Japan are outlined with a major emphasis on the transnational exchanges among them in the past and present, resulting in the basic sharing and yet stark differences in sociocultural institutions, such as religion. Instead of envisioning these cultures as hermetically sealed and localized, this article points to the internal diversities, including minorities, and diasporas and transnationals, on the one hand, and global influences on these peoples and their cultures. Nationalisms within each society are discussed in relation to the colonialisms by Western and Japanese empires in the past.

Recent developments in the studies of East Asia parallel many significant paradigmatic changes in the behavioral and social sciences in general, serving as windows of opportunity for raising new questions and issues and engaging in fruitful comparisons with research in other parts of the world. A number of productive directions have opened up because the terms and concepts in social sciences came under scrutiny, offering us opportunities to reconceptualize how to approach and study 'people', 'culture', and 'society', without treating them as homogeneous and bounded entities. Increasing attention to power inequality within a society – be it as small as a family or as large as a nation-state – and without – external geopolitics has sensitized the studies of East Asia so that a microstudy of a social group is linked to macro scenes of political economy both within the society concerned and without, leading to fruitful cross-disciplinary approaches and comparative studies with other areas of the world (Anagnost, 1997). In this context, the West, which served as a mirror for East Asian peoples for a long time, is now being reconceptualized so that dynamic relationships among East Asian cultures and peoples, within the context of world history, are receiving more emphasis than in the past (Wang, 2014).

'East Asian Studies' is a well-established area studies program with a long and distinguished tradition of studying the peoples of East Asia and their lives. 'East Asia' appears to be a fairly well-demarcated geographical area, consisting at present of the People's Republic of China (mainland China, now including Hong Kong), the Republic of China (Taiwan), North and South Korea, and Japan. However, shifting political boundaries – even at the start of the twenty-first century – and recent epistemological and theoretical questions in various fields have reminded us that 'East Asian Studies' is a highly complex undertaking. Building on excellent studies of the peoples of East Asia and their cultures, the field is now invigorated by fresh insights and perspectives.

Nonlocalized Cultures

Historically the Chinese, Korean, and Japanese 'civilizations' have had much in common, to a large measure due to the diffusion of the Han and Tang civilizations from China to the rest of the area, where each local tradition has significantly transformed these influences. Linguistically, the Sino-Tibetan languages, all of which are characterized by the tonal system (whereby tones give distinctive meanings to the same sound types), belong solely to the Chinese. The Korean and the Japanese, together with the Ainu and Gilyaks, come from an altogether different, nontonal, linguistic stock. Yet the Chinese writing system was adopted and superimposed on the spoken languages of the Korean and the Japanese, although both added their own systems at a later time.

Recent changes of emphasis and perspective in East Asian Studies derive from criticisms of, and even some frontal attacks on, the concept of culture, the most fundamental concept in anthropology, though it has come under attack in recent decades. Nonetheless many continue to find 'culture' concept useful, together with 'society' and even 'nation', not as hermetically sealed, but, pulsates in the vertigoes of world history and always transforming at the confluence of internal/local historical development and external/global historical forces. Almost all major foundational features of Japanese culture and political economy came from the Asian continent, usually via Korea. They include the 'wet-rice economy' in early times, and later – during the fifth and sixth centuries – Buddhism, the imperial ritual, the writing system, city planning, metallurgy, and a host of other activities. Since the end of the nineteenth century, the major influences came from Euro-American cultures.

Japan's first legal system, instituted first in CE 645 through the so-called Taika Reform, was based on the political system of the Tang Dynasty. The draft of the Meiji constitution, promulgated in 1889, was drawn up by primarily German and French legal scholars, with the Prussian constitution as their model. Many of the key articles were adopted almost verbatim. The current constitution was 'given' by the American government at the end of World War II. Indeed, the modernization in Japan, as in other Asian countries, was, to a great extent, Westernization. No society is an island in history. Hybridity is a *sine qua non* of any culture. Astronomically fast cyberspace communication today makes us keenly aware of the basic nature of culture as a dynamic, unending process of the interpenetration between the local and global.

Dynamics Within

A powerful critique of the notion of culture in the past as a 'totalizing' and 'essentializing' representation of a people or a culture led our studies in several productive directions. One such direction is the further emphasis on diversity, multiple voices within an artificially demarcated unit of our study – be it a people, a culture, or a society – resulting in a plethora of research on social groups other than the dominant ones (Feuchtwang and Wang, 2001; Slater and Ishida, 2009). These groups include not only the so-called minorities but also the homeless, school dropouts, etc. This move is a corrective to the representation in the past, for example, of the Chinese by the Han Chinese, or the Japanese as the agrarian Japanese: the emphasis on the latter led to a label, 'rice paddy courses', referring to introductory courses on Japan. The recent research on minorities places these social groups not as isolated groups but in relation to dominant social groups, especially but not exclusively in regard to power inequality between the dominant and marginalized social groups.

In the case of Japan, wet-rice agriculture, which originated likely along the middle Yangtze River, reached northern Kyūshū some time around 350 BCE. Called Yayoi culture, it supplanted the Jōmon culture based on foraging economy of the first occupants of the archipelago, who had arrived there around 200 000 BCE (Kobayashi, 2003). It laid the foundation for the political economy of the Yamato state and the imperial system. Gradually the segment of the population engaged in rice agriculture – or, more accurately, who reaped the economic/financial crop from wet-rice economy – became the dominant social group, representing 'the Japanese'. The agrarian cosmogony and cosmology became those of the Japanese, whereby the rice agrarian seasonality governed all Japanese and rice paddies came to represent the Japanese space.

There is an increasing awareness now among scholars that the other side of the development of 'Agrarian Japan' was the marginalization of 'the Japanese' in nonagrarian sectors. They included those people whose livelihood derived from the resources of the sea and the mountains. In particular, this included what later became known as the 'hisabetsubu-rakumin' (settlement people under discrimination). These were people who engaged in nonagrarian occupations such as performing arts, architecture, and trading, plus itinerant religious specialists, who, from late medieval times – when the notion of impurity received radical negativity – became increasingly marginalized, until 1582 when they were codified as two categories of 'outcasts'. The marginalization of the Ainu, who continued to engage in hunting, fishing, and plant gathering well into the nineteenth century, was similarly based on the yardstick of agrarian values, which placed emphasis on plant domestication. In addition, the assignment of 'primitiveness' to them was a by-product of the Japanese, who tried to 'modernize' their nation according to the model of Western modernization (Ohnuki-Tierney, 1987, 1993).

A related development is an emphasis on women – their voices, their life experiences, and women as social agents who actively carve out or change the courses of their lives in a globalized society (Abelmann, 2003; Ngai, 2005). The issue of gender preferences, both institutionalized and culturally sanctioned as well as individual, has also received considerable attention. Gender-related issues often address the question of gender inequalities, which are in turn juxtaposed with the power inequalities between classes within society, on the one hand, and between the colonizers and colonized, on the other, breaking new ground for various disciplines.

Diasporas and Transnationals

Another major critique of culture is how it was presented in the past as being spatially bounded and tied. The nonisomorphic nature of the cultures, locality, and peoples of East Asia was realized early by scholars of East Asia, who have contributed to the studies of 'overseas communities' (e.g., Chen 1939) – numerous 'Chinatown' studies, Japanese Brazilians (Tsuda, 2003), and the like. Scholars of 'transnationalism' study emigration, the resultant overseas communities (some diasporic), and 'transnationals' with 'flexible citizenship' in the – contemporary context of globalization, which created an unprecedented flow of population across borders of nation-states (Ong, 1999). The recognition of the nonisomorphic relationship between a political unit – such as a nation-state – and a people/culture became more than obvious in East Asia when 'the Chinese' were divided into those in the People's Republic of China, those in Hong Kong – first under the British and then the People's Republic of China – and those in the Republic of China (Taiwan) across the Formosa Strait. Likewise, 'the Koreans' were split into North and South. Japan, which has been stereotyped as homogeneous in terms of demographic composition, has been a heterogeneous population throughout history. But, to give one example, in 1940 the then prime minister of Japan, Konoe Fumimaro, delivered a now infamous speech that "one hundred million Japanese with one soul" be dedicated to the service for the Emperor. This figure included 30 000 000 Koreans, Chinese, and others who resided in Japan and its occupied territories, who were given an equal right to death, that is, from 1944 they were forced to become Japanese with the Japanese soul in order to be drafted to fight for imperial Japan (Ohnuki-Tierney, 2002). This is not to mention the diversity within the so-called Japanese, with the Ainu to the north, and the Okinawans to the south, who were once thought of as distinct from those on the main islands, and 'Westerners', including the 'White Russians' and Jews.

The political mosaic in East Asia offers a fertile ground for studies of 'identities' and conflicts among social groups within a nation-state and between nation-states. Within a nation-state, the majority vs minorities are interlaced with the question of what makes a social group 'ethnic' (the Okinawans in Japan 'used to be' ethnic); whereas the two Chinas and two Koreas present a different situation – the question of two nation-states consisting of one people. In other words, East Asia offers a microcosm of what we see in the world in which the same collective identity is held by people in different locals.

Nationalisms, Colonialisms, and Imperialisms

Research on the complex problem of identities in East Asia will join the now burgeoning field within social science of ethnicity,

nationalism, and ethnonationalism, as well as a more legally defined 'citizenship'. Ethnonationalism is 'the politicization of ethnicity', related to 'the generation of regional or subnational reactions and resistances to what is seen as an overcentralized and hegemoic state' (Tambiah, 1996). Colonialism in East Asia is another genre of research in which interest is growing, and which promises a rich source of comparative work. Studies of Western colonializations have yielded rich fruit for scholars in the past. The Opium War (1839–1942) and the resultant cessation of Hong Kong became the symbol of the power of Western (British) colonialism over Asia, whereas the Boxer Rebellion (1899–1900), crushed by the combined forces of Western and Japanese powers, foreshadowed not only Western but Japanese imperialism; the latter leading to the colonization of a large part of Asia, with its worst case in Korea (1910–45) (Duus, 1995), These studies offer important comparative bases for Western and non-Western colonializations in Africa, the Americas, and other parts of the world.

At the level of nation-states, the identity of a people could be expressed through peaceful 'cultural nationalism', which defines and represents a people of a nation-state as distinct from the 'other(s)', often those who, physically or symbolically, press at the 'border' – figuratively and politically. Thus, when the Japanese began to emerge from their total immersion in the Han and Tang civilizations of China, they began to assert their own culture, switching from embracing the Chinese aesthetics of plum blossoms to that of cherry blossoms as their flower. Since the mid-nineteenth century Japan's nationalism, both cultural and political, has been informed by paradoxes and ambivalence of the Japanese's own identity, which was formed in part by rejecting Western political imperialism – while at the same time eagerly emulating Western civilization – and in part by rejecting their own Asian identity – while seeking it in order to establish a difference from the West.

Cultural imperialism is a genre that has not yet received systematic attention. Political domination by Western European nations (but also Japan to a lesser degree) led to the cultural mirror to emulate for many Asian peoples who are often eager to adopt not only Western science, technology, and capitalism, but almost everything from the 'West' being revered, including foodways, the body esthetics, resulting in skyrocketing sales of cosmetics and plastic surgeries. Even before affluence led the Japanese to seek out designer names such as Gucci, Bally, and Louis Vuitton, American Revlon lipsticks, and Ivory soap were far more expensive than their domestic counterparts and were preferred as gift items.

This is an important area of study, not only because it offers us a valuable window onto the other side of political colonialism but also because it constitutes a significant dimension of the current globalization, in which the notion of brain death, organ transplantation, human rights, environmental conservation, and the like, which involve concepts and values that are predominantly Western in origin, are adopted outside their areas of origin. Medical high technologies, saluted as the golden achievement of Western biomedicine, bring prestige to those in another society who embrace them as being 'progressive', although such technologies may require not only radical reconceptualization about the death in relation to the body but also mortuary rituals, with beliefs, values, kinship, and a host of other important dimensions for a people (Ohnuki-Tierney, 1994).

Global Forces

The 'nonlocalized culture' presented earlier is in part facilitated by transnational forces that had been quite strong and intensive among East Asian societies from very early on. Despite difficulties involved in travel at the time, people, including scholars and religious specialists, frequently traveled between these three countries, resulting in a great deal of sharing among Chinese, Korean, and Japanese cultures. Buddhism, originally from India, traveled from China to Korea and Japan. In Japan, Buddhism made an enormous impact, not only on the indigenous religion of Shintoism, but also in visual and performing arts, rock garden, and a host of other intellectual and cultural activities. Confucianism, originally developed in China, established the strongest hold in Korea. One cannot ignore, on the other hand, the impact of 'Western' religions. The institutionalized Christianity is extremely strong in Korea, whereas it penetrated into Japanese culture intensively, though not retaining the institutionalized forms. On the other hand, many influential intellectual and political leaders of Japan since the Meiji restoration in 1868 have been devout Christians, some of whom assumed important roles as intellectual and moral leaders of the country.

The present globalization is marked by the spread of high technology and market economy of late capitalism. The global flows of people are studied as research on tourism, diaspora, and transnationals. The flows of goods and signs/symbols are studied through research on global dissemination of youth fashion, fast food, television programs, films, pop music, and a host of other things that are engulfing the globe. Most originate in the West, but some, such as reggae, do not. The studies of the introduction of McDonald's – a symbol of postmodern fast-lane life in the USA and an epitome of Americana for peoples elsewhere – show a simultaneous transformation of the locale, which in turn transforms the fast food in significant ways.

Without denying the importance of an unprecedented flow of people, goods, and signs, others urge us to compare the present with the past when spice trades, capitalism, colonialism, features of Western High Culture, etc., spread throughout the world. In short, East Asian cultures and peoples have been 'globalized' for a very long time.

Cultural, Social, and Political Institutions

East Asian studies continue to produce distinguished scholarship on: kinship and social organization; religions (beliefs and rituals); educational systems; visual and performing arts; and health-care systems. Excellent studies of the institutionalized religions of Buddhism and Confucianism, shared by most Asian societies in variant forms, and of Shintoism in Japan describe how they have impacted on sociopolitical organizations as well as arts and science. They also tell us how people experience these religions in their daily lives. The emphasis on the impact of religion in individual lives receives the attention

in the studies of 'ancestor worship' shared by most peoples of East Asia (Ahern, 1973; Janelli and Janelli, 1982; Smith, 1974). 'Ancestor worship' is a misnomer but refers to the practice of taking care of the souls of deceased family members and relatives through a long series of rituals. Despite profound changes that such worship underwent in each society, it remains perhaps the most important aspect of religious beliefs and rituals in these societies. Shamanism and other religious beliefs and practices that have been regarded not to belong to institutionalized religions are also well studied in relation to the day-to-day lives of contemporary peoples. In contemporary Korea, for example, shamanism is of exceptional importance and recent studies highlight the role of women in Korean shamanism (Kendall, 1985). Although their pervasive influence is less recognized, Taoism and geomancy, as practiced in China and spread to Japan, constitute important dimensions of cosmology comprising symbolic oppositions (expressed in yin-yang) and remain important in the daily lives of people in East Asia.

The academic study of health care has a long tradition in East Asia. 'Chinese medicine' in particular has received attention from distinguished scholars such as Joseph Needham, who explicated how their medicine constitutes a science distinct from Western science (Needham, 1969), and Manfred Porkert, who later produced a similarly distinguished work (Porkert, 1974). Contributors to Kleinman (1976) volume focused on doctors, patients, and their interactions, rather than medicine as a system.

Abstract

This article provides a comparative analysis of the dynamics and challenges of East Asian economies. These economies have undergone a radical transformation since the early 1970s that have shifted the balance of power both within the region and in the global economy more broadly. The first major change that characterizes this period is the rise of the newly industrial economies of Taiwan, South Korea, Singapore, and Hong Kong. The second major change has been the transformation of China's planned economy. The successes in various development projects in these economies have been tempered by economic challenges in the region, namely that of Japan in the 1990s, the Asian financial crisis of 1997, and the considerable challenges still facing the Chinese reform effort, all of which have shown the vulnerabilities of this regional economy.

The Newly Industrialized Economies

The rapid development of East Asian economies – the advanced industrial economy of Japan, the newly industrialized economies (NIEs) of Taiwan, South Korea, Singapore, and Hong Kong, and China's transitional economy – have made this region one of the most dynamic in the global economy. In the latter half of the twentieth century, Taiwan, Singapore, and Hong Kong were among the most dynamic economies in the world, having leapt, in the postwar period, from the status of poor underdeveloped to strong industrialized economies (Clark and Roy, 1997), and their patterns and trajectories of change challenged conventional wisdom about how developing nations modernize and industrialize, and about the role of the state in these processes of change. The three decades following World War II were a period of enormous enthusiasm about the economic prospects for developing countries. These were the years when a large number of such countries embarked on ambitious projects of agricultural and industrial modernization. Indeed, it was this effort that gave rise to 'development economics,' and more broadly, 'development studies,' as new disciplines in the social sciences. In the halcyon years of development planning, most eyes were focused on the larger or more industrialized countries such as India, Brazil, Mexico, and Egypt. Few expected very much, if anything, from East Asia, large areas of which had been colonized by Japan in one way or another in the first half of the twentieth century, and parts of which seemed hopelessly backward. Taiwan had a minuscule industrial base in 1950, Hong Kong and Singapore were tiny city-states, and South Korea seemed to be sinking in a morass of corruption and inefficiency by the end of the 1950s. Yet, a quarter of a century later, the tables had been turned: East Asia emerged as the economic 'miracle' of the postwar period, witnessing some of the fastest growth rates of the modern epoch, while Latin America and South Asia were mired in political and economic crises. Given this regional growth phenomenon, does it make sense to talk of an 'East Asian Model?' There are some important similarities in development strategies across the cases, enough to persuade many commentators that the appellation is warranted. But there are also interesting differences that are worth noting.

Among the East Asian NIEs, South Korea and Taiwan have attracted the most attention. Over the years, two general views have emerged about the reasons behind their spectacular economic success. One, which was perhaps the dominant one for much of the 1970s and 1980s, held that the two countries were successful because of their fidelity to free-market policies, particularly an open trade regime (Lal, 1985; Bhagwati, 1988). But this view has come under a great deal of criticism from many quarters, and a new argument has emerged in recent years, which offers a different explanation for Korean and Taiwanese success. In some ways, the two countries achieved their remarkable economic success the 'old-fashioned' way: both started with highly successful land reforms, which immediately set them apart from much of the developing world; both managed to bring about extraordinarily high savings rates, which were then channeled into correspondingly high rates of investment. But the two countries did not simply grow by increasing the rate of accumulation. They also succeeded in acquiring, and then unpacking, technology from advanced industrial countries, so that they were able to move up the production chain into manufacturing and exporting high value-added goods. The involvement of the state was crucial to this process (Gold, 1985). First, both governments launched highly effective campaigns to increase literacy rates, which accounted for a highly educated work force (World Bank, 1993).

Furthermore – and this has been one of the most heralded facts about their experience – the two states played a crucial role in facilitating the acquisition and transfer of imported technology. These technologies were brought in sometimes through foreign direct investment, but mostly through licensing agreements with multinational corporations (MNCs). Agreements were carefully crafted to ensure that foreign partners did not simply hand over obsolete technology, and that local engineers were able to acquire blueprints as well as the training necessary to master the technology. Firms were also encouraged, assisted, and even coerced to produce for export markets, in order to submit them to the rigors of international competition (Amsden, 1989; Wade, 1990). Success in export markets was used by both states as a benchmark for efficient production. Even firms producing mainly for the domestic market often had to show export success in order to be granted credit, investment licenses, and other state benefits (Aoki et al.,

1997). Finally, the state was active in maintaining, for many of the crucial years of take-off, a tightly policed and powerless labor force, which added to the 'flexibility' of production.

While South Korea and Taiwan shared these elements in their development strategies, they also exhibited some important differences. Korea emphasized a reliance on the private sector, which was not only encouraged to grow, but also to become increasingly concentrated. In this, it resembled the Japanese experience: the Korean economy was dominated by a small number of highly diversified business groups, known as the Chaebol, which together accounted for the majority of the country's domestic product. The Chaebol quickly emerged as the pivot on which industrial policy turned, establishing a close working relationship with the ruling regime (Amsden, 1989). The Taiwanese state, on the other hand, did not have such a close relationship with private capital. Taiwanese planners relied much more on a large agglomeration of state enterprises as the nucleus for development policy; private capital was influenced – in comparison with the Korean case – more through pricing and procurement policies than by direct negotiation. The private sector was, in turn, not actively encouraged to become highly concentrated. Taiwanese industry was, much more than its Korean counterpart, characterized by small enterprises (Wade, 1990). Nevertheless, a kind of quasi-corporatist structure was used to bargain with some sectors. Indeed, in both countries, a similar structure was put to use for this: firms in targeted sectors were organized into sectoral or trade associations, which were given the right to bargain with the state (Fields, 1995). The overall complexion of industrial policy, however, remained visibly different in the two cases, with Korea relying on a highly concentrated private sector, and Taiwan more on state enterprises and small firms.

Singapore and Hong Kong are usually regarded as contrasting cases to Korea and Taiwan, in that whereas the latter two are examples of state-led development, the former pair embodies a free-market path – or so the story goes (Rabushka, 1979). There is some element of truth in this. Hong Kong, in particular, did not experience anything like the selective industrial policy witnessed in the larger countries. And both of the city-states were much more open to foreign direct investment than was either Korea or Taiwan. But there are important respects in which the city-states converged with the experience of their larger neighbors. First, like Korea and Taiwan, both Hong Kong and Singapore actively suppressed labor rights. Second, the state was of some importance in facilitating industrialization. Singapore, despite being more open to foreign investment, relied greatly on state enterprises to facilitate the entry of MNCs by forming partnerships with them, hence reducing the risk of such undertakings; further, the domestic market was not thrown open to imports, and was protected much like that in Taiwan and Korea. Local firms were also offered carefully targeted fiscal incentives, under the guidance of an Economic Development Board. Hong Kong was, of the four, the furthest away from the interventionist model. But here, too, the state played a crucial role in solving a host of collective action problems for local firms: most directly through its considerable expenditure on infrastructure, training programs, and, perhaps most importantly, its massive socialization of wage costs through the construction of an extremely generous welfare state. Between 1949 and 1980, government expenditure in Hong Kong grew by 26 times, and expenditure on welfare by an amazing 72 times (Castells, 1994). This was absolutely crucial to the success of Hong Kong exports, in lowering the wage costs to producers.

In sum, despite their differences, the four cases do exhibit certain important similarities. Perhaps the most important of these is the critical role played by the state in fostering the transition to highly productive industrialized economies. The differences lie mainly in the instruments used by the various regimes: selective intervention in the larger two countries, and more macro-level policies in the smaller ones.

China's Transforming Planned Economy

While the NIEs were executing successful development processes, the first three decades of Communist Party rule in China (1950s through 1970s) were organized around the establishment of a socialist planned economy (also called a 'command' economy). In this system, markets were eliminated and replaced by governmental plans that guided the economic decisions of enterprises and individuals. China's one-party government replaced private ownership with state ownership, established economic targets for industrial enterprises, and set up collective farming in the agricultural sector. Economic agents (whether industrial enterprises or farmers) were instructed to whom they would sell their goods and for what price. Revenues were then collected by the government and redistributed to enterprises and individuals in the economy. This system was thus more than a purely economic system; it was also the basis for the social security system in China (Walder, 1986; Whyte and Parish, 1984).

Without a competitive marketplace to regulate and guide economic behavior, planned economies, such as China's, are often rife with inefficiencies. In 1978, after a decade of upheaval wrought by the Cultural Revolution, the 'Ten Year Plan' of 1976 was already faltering, and the need for some degree of economic reform was clear. Following a political struggle that pitted reform-minded Deng Xiaoping against the economically conservative Hua Guofeng, Deng Xiaoping took control of the economy in late 1978 at the Third Plenum of the Eleventh Central Committee of the Chinese Communist Party. Once in control of the government, Deng launched China on a path of economic transformation.

One of the central debates in research on transitions from planned to market economies revolves around the extent to which privatization is a necessary part of this process. Some scholars have argued that without rapid and complete privatization – the so-called 'shock therapy' approach to reform – true economic reform is impossible (Kornai, 1990; Sachs and Wing Thye, 1994). Other scholars have argued that China is the case that disproves this view: in contrast with the rapid changes that characterized the economic reforms of Russia and Eastern Europe, China's reforms have been introduced in a gradual and stepwise fashion, where the government has experimented with new economic policies and incrementally implemented the successful practices on a wide scale (Naughton, 1995). Proceeding in this gradual fashion, the Chinese transition to a market economy has been unquestionably the most successful in the world. (China sustained the fastest rates of growth in the

world for the first decade and a half of economic reform. Throughout the 1980s, its real gross domestic product (GDP) grew at an average annual rate of 10.2%, a level that was equaled only by Botswana. From 1990 to 1996, the average annual rate of growth for real GDP was 12.3%, the highest rate of any country in the world for that period. It has also had the highest industrial growth rate (an amazing 17.3% average annual growth, 1990–96) and the second highest growth in services (9.6% per annum, 1990–96) in the world.)

In the industrial sector, often regarded as the backbone of the Chinese economy, five key changes have reshaped this system. First, the government gradually removed itself from day-to-day decision-making, effectively placing the responsibilities of economic decisions on the shoulders of industrial managers. In the early years of the reforms, enterprises were still expected to produce a certain amount of goods for the government's plan, but anything they produced above this residual plan they were allowed to sell in China's emerging markets. This transitional system was called the 'dual-track' system (Naughton, 1995). Second, a private economy was allowed to emerge to compete with the state sector, a factor that was critical for the creation of a competitive marketplace. Thus, while privatization was the cornerstone of industrial reform in other transforming planned economies, Chinese firms were introduced to market economic behavior without privatization (Rawski, 1994), and state firms eventually 'grew out of the plan,' producing an increasing proportion of their goods for the marketplace (Naughton, 1995). The success of this transition, however, has varied in accordance with a firm's position in the former command economy: firms under township and village governments, most of them the so-called Township and Village Enterprises (TVEs), have been managed closely by local governments and thus have weathered the reforms much more successfully than those under the central and municipal governments (Walder, 1995).

A third change that has defined China's economic reforms is that foreign investors were allowed in the Chinese economy for the first time since the communists expunged the foreign presence in the early 1950s. This factor has been very important for the transfer of technology and the transfer of international management practices. Fourth, the government adopted a decentralized and piecemeal approach to development regionally: in the late 1980s, the government adopted the coastal development strategy, in which the goal was 'state-directed' export-oriented growth (Yang, 1991). Finally, Chinese enterprises have been relieved of their responsibilities in the provision of social security benefits to their employees and, perhaps more significantly, they are no longer required to make lifetime commitments to the workers they employ. In the agricultural sector, a similar process of change has unfolded where farmers have been given the freedom to sell whatever they produce beyond the plan in the marketplace, until eventually the market has overtaken any vestiges of an economic plan in this sector. All of these economic changes have been formalized through the passage of some 700 national laws and more than 2000 local laws (Pei, 1994).

Transforming the planned economy of the world's most populous nation has been a complex process and is far from complete. Nevertheless, the first two decades of transition from plan to market have been impressive and, compared to the reforms in Russia and Eastern Europe, a dramatic success. For the first decade and a half of economic reform, China had the fastest growing economy in the world, sustaining double-digit growth figures for much of the 1980s and 1990s. Where it was a third-world developing economy as late as the early 1980s, by the beginning of the twenty-first century China had the seventh largest economy in the world overall in terms of GDP, and it is second only to the USA when GDP is adjusted for purchasing power within the country. (For example, if a bushel of rice costs half as much in China as in the USA, then a unit of currency is twice as valuable there. GDP statistics can, when appropriate, be adjusted for 'purchasing power parity' (PPP): a statistic that adjusts for cost of living differences by replacing exchange rates with relative measures of local purchasing power.)

Among the challenges that still lie ahead are the continued reforms of the state sector – the leviathan organizations that remain inefficient and insolvent after more than 20 years of reform; the continued reform and clarification of property rights; the liberalization of several critical sectors, such as the telecommunications sector, and the development of the western provinces, which have fallen far behind the development in the eastern coastal region.

Japan's Lost Decade and the Asian Financial Crisis

It is, in part, because of the great successes of development in East Asia that recent economic crises have hit the region so hard. Two related, but distinct, economic crises are worthy of note here. The first is the economic downturn that Japan suffered in the second half of the 1990s. The second is the Asian financial crisis, which gripped much of East and Southeast Asia in 1997 and 1998.

Japan was, for most of the postwar period, one of the fastest-growing economies of the industrial world, racking up huge rates of growth year after year until it had achieved its current position as the second largest economy in the world, with an annual GDP of more than $5 trillion. Its economy was the engine for the broader regional development of East Asia, both through its capacity as a market, and as a source of capital and technology. A more intangible, but nevertheless important, role was that it provided the model on which the two Northeast Asian 'tigers' – Taiwan and South Korea – based their economic strategies.

By the end of the twentieth century, however, the Japanese dynamo seemed to be losing its energy. It spent most of the 1990s mired in an economic recession that turned out to be the longest and most severe in its postwar history. The precipitating event behind the crisis was the collapse of the asset bubble of the 1980s, which burst in the beginning of the next decade. The bubble itself had been built up during the 1980s as the Japanese state had initiated a policy to ratchet upward the domestic rate of investment and make the economy less dependent on external markets. Spurred on by the constant pressure by the USA, to raise the value of the yen, the Japanese government moved, by the late 1970s, to trigger a massive investment drive by raising the value of domestic assets. At one level, it worked very well – as asset prices rose, Japanese firms launched a massive drive to retool and invest in new technology. But the flow of investment soon exceeded anything that actual returns

could justify, driving up asset prices steadily into a speculative bubble. Sooner or later all speculative bubbles burst, as did this one in the 1990s. And once the bubble burst and the economy slowed, firms found themselves stuck with massive over-capacity and onerous levels of debt. Through much of the decade, business and residential investment continued to fall, throwing the economy into a downward spiral.

The Japanese downturn was one of the background factors that laid the conditions for the East Asian crisis of 1997–98, which is now regarded as the most significant economic catastrophe the world has seen since the Great Depression. As the economy slowed down, firms compensated by turning outward, into a massive wave of investment in Southeast Asia. This led, in turn, to a process not unlike that was witnessed in Japan: corporations went into deep debt to pay for new investments, leading to the build-up of extraordinary industrial capacity; after a point, money also began to pour into real estate and other forms of wealth, driving up their prices until a speculative bubble was created reminiscent of the Japanese bubble.

Although much of East Asia had bounced back from the Asian financial crisis by the spring of 2000, this crisis revealed some weaknesses in the rapid development of the 'Asian Tigers.' The crisis itself was set off by currency devaluation: in the spring of 1997, as the pace of growth in the Thai economy fell below projections, currency investors began to speculate against the baht in hopes of profiting from the inevitable devaluation of the currency. When the currency devaluation came in July, foreign investors fled from Thai markets, and similar behavior spread quickly throughout the region. Stock prices plummeted, currencies went into free fall, and banks began to call in loans that their customers – many of them large corporations – could not repay. By the end of 1997, the International Monetary Fund had bailed out Thailand, Indonesia, and South Korea with $17 billion, $43 billion, and $57 billion, respectively.

Two explanations have been advanced to account for the crisis. In one view, an over-reliance on foreign capital and international institutions, changes in regional economies – namely China's and Japan's – and reliance on the dollar brought about the crisis (Ahn, 2000). First, the strength of the Japanese yen in the 1980s and that of the dollar in the 1990s led to excessive foreign investment in the strong East Asian economies, particularly for Japanese investors. As local banks sought strong currencies, investment and lending agreements were structured to attract these foreign players, and excessive capital led to high-risk investments, many of which would prove to be insolvent when the crisis stripped the veneer of economic discipline. Second, as China's economy began to expand, it took over a large share of the export market, the centerpiece of development for many East Asian Economies. Third, when European currencies depreciated against the dollar in 1995, dollar-pegged East Asian currencies appreciated – relatively speaking – leading to a decline in exports. Fourth, as the flow of international capital increased through such institutions as hedge funds and short-term loans, speculative behavior on the part of international currency investors in these rapidly expanding financial markets led to market volatility.

A second explanation acknowledges the problems listed above, but places the blame of the crisis on the East Asian economies themselves. This explanation often veers into a cultural argument about the prevalence of 'crony capitalism' in the region. In this view, the East Asian business model, often led by government-directed investment in key industries, is also often built around implicit guarantees from the government for the liabilities of local financial institutions (Krugman, 1998). Thus, the so-called 'soft budget constraint' (Kornai, 1994), which was the hallmark of planned economies, some economists argue, was also fundamental to the East Asian business model more generally. Governmental guarantees led to risky behavior on the part of financial institutions, which ultimately led to the financial crisis itself.

The Balance of Power: Regionally and Globally

Despite the economic crises experienced in the region in the 1990s, overall the second half of the twentieth century saw a dramatic shift in the economic balance of power both intra-regionally and with regard to Asia's position globally. Within the region, while Japan was far and away the economic powerhouse of the region by the end of the 1980s, at the dawn of the twenty-first century the balance of power looked very different. Partly because of the rise of the NIEs, but perhaps more importantly, because of the dramatic growth of China's economy, Japan's economic dominance in the region has unquestionably waned. It is difficult to predict what the exact economic balance of power will be within the region in the coming decades, but it is certainly clear that China will challenge Japan as the center of the Asian economy. In particular, the conflict between Russia and Ukraine, and the ensuing worsening of relations between Russia and the European Union and the USA, is leading Russia into greater dependence on China as a market for raw materials, especially oil. A major oil agreement between China and Russia might lock Russia into the position as a relatively cheap supplier of hydrocarbons – and this, coupled with China's increasing investment in alternative sources of energy, might further facilitate China's potential for continued growth.

Globally, the economic balance of power has shifted as well. While Japan has been counted among the Group of Seven (then Group of Eight, and again Group of Seven) industrialized nations since the organization's inception, during most of the twentieth century Western economies have dominated the global scene. However, with Japan and China both among the top 10 largest economies in the world and four Asian economies among the top 20 (five if we include Australia), and with China poised before long to have the world's largest economy, Asia is certain to play an increasingly important role in the balance of the global economy.

Abstract

Gender, like all ideological terms (e.g., civil society), is political policy and an analytic category. Here gender in East Asian studies will be understood historically. A concern of anthropologists, sociologists, and political economists since the 1970s, the use of a gender analytics was contested when it entered East Asian area studies in the 1990s Conceptually (and particularly after several historians refined and popularized the term), gender offered a social explanation for cultural variation in sexual and social practices previously either attributed to anatomical difference or simply ignored. It also offered a mode of general cultural analysis. Approximately when gender was accepted into area studies, 'East Asia,' an artifact of Cold War area studies in the United States, began to be questioned. In post-1989 re-regionalized area studies the preferred scholarly term is 'Asia-Pacific.' Factors contributing to re-regionalization are common: unequally experienced neoliberalist economic globalization processes; intrastate capital development projects; transnational flows of Chinese gendered labor and capital; and, the new global division of labor linking South East, East, and North Asia. While regional states retain sovereign regulatory powers, the national welfare policies that during the twentieth century provoked and circumscribed national gender stereotypes and development policy are changing. In 'new metropolises' that form the skeleton of the Asia-Pacific, neoliberal economic policies still shape national or race, ethnic, gender-coded citizens. However, driving ideologies of gendered social difference now are commodified, consumption-oriented, lifestyles. New policies, practices, and critical theories in turn are reshaping how area scholars and government officials employ the gender analytics now.

The Concept of 'Gender'

Gender is an analytic term that came into common academic usage in the late 1970s and early 1980s in the United States among feminist social scientists. The widely influential historian Joan Scott urged historians to use the term gender to describe women's social and historical differences from men positively (Scott, 1986). By the early 1990s, debate over the gender concept had widely expanded. Judith Butler's theoretical work (1990) established gender to mean the cultural practices that make sexual natures of all kinds appear to be fundamental, heterosexual, and unchanging. Simultaneously a publishing boom of high-profile volumes began that, over the 1990s, has firmly secured the notion of gender into questions of national or political difference. Other volumes (e.g., Sangari and Vaid, 1990; Gilmartin et al., 1994) have linked the gender concept to the problem of colonialism in what have become the fields of postcolonial studies, comparative feminism, and gendered area studies.

The Policies of Gender

Gender is modern political policy. Presently it forms an element of the post-Cold War global governance goals disseminated through the United Nations, so-called nongovernmental organizations, and donor or civil society organizations. This post-1989 neoliberal gender policy is juridical. It argues that all states should adopt the position that women's rights are universal human rights. Gender as state policy, however, is older and more historical than current rhetoric would have it. In the twentieth century, industrialized and late industrializing states have cast citizenship in gendered terms.

Contemporary Gender Policy, Global Governance, Women's Human Rights, 1979–

The importance of gender as policy emerged in the initiatives for global governance over the last quarter of the twentieth century. It is an aspect of the international human rights law movement. Its cornerstone is the Convention on the Elimination of All Forms of Discrimination against Women, which seeks to abolish 'gender-based violence' and is a 1979 revision of the 1948 Universal Declaration of Human Rights. The United Nations, donor agencies (like the Ford Foundation), and a newly arisen civil society sector began advancing gender-sensitive programs during the United Nations Decade for Women (1975–85) and during subsequent United Nations Conferences on Women, culminating in the 1995 Beijing Fourth World Conference on Women and its resulting 'Platform for Action.' As a whole, these institutions and the World Bank's investments promote the view that gendered difference is an important axis of inequality. Many advocates in the United States blame non-Western states for gendered inequality. They seek to use gender as a development index to force perceived noncompliant states to redress the relative poverty and vulnerability of female citizens. Loans, investment, education, and outreach into semiofficial social service agencies are the instruments of global governance. Though a lack of clarity prevails about whether these attempts are effective or a US form of triumphalism, Charlotte Bunch and Hillary Clinton are the movement's best-known leaders.

Historical Gender Policies of Modernizing States in 'East Asia': The 1840s to the 1980s

The novelty of contemporary uses of the gender analytics tends to obscure the longevity of gender modernization policies

throughout the Asia-Pacific. Scholars working in the framework of the 'East Asian' area studies during the 1980s and 1990s have established that much (Barlow, 1996). It can be said that colonialism itself advanced the rationalization of gender by bureaucratizing social modernity or (in some cases) by directly exploiting the bodies of women. During the mid-nineteenth and twentieth centuries, the forces of imperialism, colonialism, and subimperialism propelled late industrializing states toward expeditious efforts of political modernization and capital accumulation. States pursued this objective in various ways, although interstate relations meant that events in one state (e.g., Japanese imperialism in Korea, Manchuria, Taiwan) contributed to the shape of gender policy in other states.

Colonial Gender Policy in Modern Korea

Between the 1870s, when its traders arrived in Korea's overwhelmingly agricultural economy, and 1945, when the Japanese colonial administration evacuated and the neocolonial United States occupation began, the peninsula took on the classic colonial configuration of a political economy twisted to serve Japanese imperial expansionism. Japan's colonial authorities reordered Korea's rural economy, instituting modern concepts of ownership to expedite taxation. The new system placed tax gathering and relations of production in the hands of a semicolonial and semifeudal native elite, 'landlordizing property rights.' This industry led to a widespread shift from peasantry to tenancy as the primary relation of production. Agricultural productivity rose, but so did rural immiseration. Poverty, occupation, and assimilation policies flowered into a widespread licensed military prostitution industry (see Choi, 1997). This, and particularly Japanese family law, burdened Korean gender and class relations and helped to shape a male-centered style of nationalist anticolonial struggle, involving women and men of all classes (see Park, 1998; Fujime, 1997).

In divided South Korea after the Pacific War, a state-compelled development that Alice Amsden calls 'late-industrializing' (and argues is a global model) reconfigured Korean social relations of gender (Amsden, 1989). The incorporated Cold War state inherited a Europeanized, Japanese, colonial civil code. As Hyunnah Yang has shown, along with the modern legal regulation of domestic relations the civil code supported an imaginary 'Korean tradition' that naturalized female subordination. Consolidation of Japanese domestic civil statutes and modern family law into Korean jurisprudence in the Korean Republic (during and after the partition of the nation) also ratified a gendered modernity, heavily weighted to the nuclear, patrilineal, small family unit. The now constitutional doctrine of patrilineality triggered waves of feminist intervention into state-sanctioned subordination of women and women's labor power under the US-supported military regime (Yang, 1998). Feminist and labor movement successes have led to revisions of the family law in 1962, 1977, and 1989. However, the fact remains that the modern state – more perhaps than the dynastic regime – consolidated domestic property, family jurisdiction, domestic labor, and legal claims in the hands of the patriline and restricted the claims of female kin. Little is known of the gendered state policy of North Korea, but it appears to be modeled on that of the People's Republic of China (PRC) during the Cultural Revolution (1966–76).

Colonial Modernity, Imperialist Economy, National Gender Policy in Modern Japan

Historians are agreed that the Meiji state (1868–1912) was preoccupied with gender policies from the outset of its drive to modernize Japan based on the European model (under threat of Western imperialism) (see Bernhardt, 1991; Sievers, 1983). The Meiji civil code of 1898 ideologically reformulated the patriarchal family and its relation to the state, emphasizing the political obligation of scientific housewifery, or 'good wife, wise motherhood.' Severe restrictions on women's political rights were coupled with the statist argument that the labor of women should be considered a civil service to the nation. Deliberate gender policies like these persisted, toward varying ends, throughout the twentieth century. First, the new state-sponsored industrialization policy willfully and strategically regendered the household division of labor by moving men out of domestic production into heavy industry. Second, policy affecting men and children led to the official drive in the late nineteenth century to 'reshape conceptions of womanhood' (Uno, 1991). Fostering smaller family formations, female education, young women's heavy participation in waged light industrial production, instituted bans on female public political participation, as well as campaigns encouraging feminine virtues in household and reproductive labor affected growing sectors of the national population. A 20-year effort to bureaucratize the policy on women culminated in the 1898 implementation of Japan's prewar civil code.

Capital accumulation through industrial production and constitutional state formation in Japan rested on colonial expansion onto the Asia mainland, into Korea and Taiwan, and eventually throughout the Asian Pacific. Despite its best efforts, the state had never been able to contain female wage-workers from moving into the labor market. As militarization and colonial administration drained off increasing numbers of men into service, state policy began gendering the notion of national sacrifice. Men were to provide military or colonial service. Militarized policy on women sought to rework the family into a feminine sector of the public sphere. The onset of glorification of national motherhood is datable to this era. It resurfaced (in altered form) in immediate postwar policies.

After 1945, state policy sought to emphasize domestic reproduction and superexploit male labor in an economic drive to recover Japan's regional supremacy under the umbrella of a US-dominated Cold War containment policy. An adjunct to this was an effort to limit female participation in Japan's national labor market while increasing (after 1956) women's responsibility to undertake domestic consumption responsibilities.

As in the Korean case, the history of gender and the nation sometimes precludes an emphasis on the Japanese women's rights movement, to say nothing of a transnationally influential, Japanese feminist critical theory that arose with colonial modernization and state formation. Nonetheless, as Mariko Asano Tamanoi noted in her study of rural women and nationalist ideology, the term 'national woman' is too simplistic and

does not convey the full import of gendered social change in the twentieth century (Tamanoi, 1998).

Subimperialism, Colonial Modernity, and Policies of Gender Revolution in Modern China

The Chinese record of state-mandated gender policy is intricate. That is due to its enormous size vis-à-vis other East Asia nation-states, its semicolonial status after 1842, a full half-century of multiply sited civil wars, and the high priority which the Chinese Communist Party accorded to women's liberation. As early as the compromised Republican era (1911–49), the state was initiating gender and development policies that were later absorbed into influential party state policies associated with Maoism and the revolutionary mobilization policies of the PRC.

National gender policy first appeared in the form of state-mandated reforms of education, female dress, and foot-binding practices. A juridical modernization indebted to both continental European and Japanese models was instituted in the 1929–31 modern civil code and, under the Nationalist or Republican Party state (1911–49), mobilized women into participatory forms of citizenship. A further link exists between the weakly instituted republican civil code (organized around a liberal divorce law) and campaigns during the 1940s and 1950s to propagate the Chinese Communist Party's Marriage Law (Bernhardt, 1994).

The ethos that infused revolutionary gender ideology came from the early twentieth-century Chinese Enlightenment: an anticolonial, urban, nationalist movement led by modern intellectuals. The Chinese Communist movement, which incorporated feminist themes, was – relative to contemporary states – hospitable to policies that institutionalized women's liberation. But, like other states, women's liberation became an index of national modernity, particularly, perhaps, under Chinese Communism. What most distinguished the gender policy of the early Chinese communist states was their focus on mobilization as a means of institutionalizing political policy and their organization of gender revolution around a Marriage Law that put the conjugal couple at the center of jurisprudence (Gilmartin, 1995).

Land reform and class war in the late 1940s and early 1950s and the state policy of rural communization in the early 1960s were no doubt two of the most transformative revolutions of the twentieth century. These revolutions consolidated the gains of Chinese state feminism by placing laws on the books that governed the social labor of women and granted women the rights to own (however briefly) land in their own names (Johnson, 1983). Socialist development policies, which were aimed at consolidation of state power and primitive accumulation for investment in late, socialist industrialization, rested on the nuclearization of family resources in the urban areas. They also proletarianized women and periodically used female labor as a reserve pool. The mobilization of peasant women into agricultural production furthered primitive capital accumulation as well as mechanisms to extract rural capital gains for use in urban development. Nonetheless, recent studies point to the ways that particularly poor peasants took advantage of the modern state institutions to further personal goals, particularly women seeking divorces. The socialist state's welfare policies had a wide-reaching impact on several issues: the gendering of labor, domesticity, sexuality, and demography; civil rights and access to public space; and avenues of upward political mobility.

Economic Liberalization, the Displacement of 'East Asia' as a Region, Gender Scholarship, and Transnational Flexible Economies

Just as historically 'modernization' is usually linked to Europe and the United States in the nineteenth and twentieth centuries, neoliberal 'globalization' is linked to Asia-Pacific in the last third of the twentieth and probably much of the twenty-first century. Asia-Pacific is a laboratory of post-Fordist flexible capital accumulation inside a post-Cold War international state system. The Asian Pacific roots of this neoliberal globalization lie in:

1. the Chinese economic reforms of the 1970s;
2. the hyperdevelopment of newly industrialized countries and city-states (Taiwan, South Korea, Singapore, Hong Kong);
3. Japanese capital investment in Malaysia and other South East Asian countries;
4. the rise of flexible Chinese diasporic capitalism; and
5. US-sponsored neoliberal policies of the World Bank and the General Agreement on Tariffs and Trade system.

Within intra-Asian political economies, in so-called transnational gendered labor flows, and outside it in interregional global trade, policy elites in Asia-Pacific states and national corporations are scaling back modernization strategies based on a state welfare logic (see Higgott, 1999; Ong and Nonini, 1997).

No longer central to development are the projects that had earlier supported the public ideology of a state- or nation-typical, modern woman, and domestic relations, although the use of maids among the middle class is stabilizing the elite family structure in some regions. It is premature to speculate what specific gendered configurations in subregions and specific locales will emerge in the future. However, gender is becoming a central concept in writing throughout the Asia-Pacific region and the United States. Scholars globally seek to explain how liberalization of economic life affects populations that are now defined in relation to their consumption power or their capacity to be absorbed into the flexible service sector (e.g., tourism, prostitution, travel) as well as their labor power. Heightening class differentials separating consumers and service providers, surging global inequality explained in cultural terms, ethnic and race-coded discriminations, systematic preference accorded flexibility in labor migration, and capital investment patterns across statelines (but within regional cores) are all having an impact on the way that the concept 'gender' (in Chinese usage 'social gender' or *shehui xingbie*) will be employed. Transnational corporations now recruit and market with the concept in mind. New social movement policy strategists, networks of internationalist progressive scholars, US feminist human rights lawyers, World Bank lending policymakers, United Nations monitors of prostituted labor and infectious

diseases: all are incorporating the policy and analytics of 'gender' into their thinking.

Particularly since the finance capital crisis of 1997–98, it has been increasingly apparent to observers that a new regional production of scholarship is on the rise. Produced by diasporic scholars from Asian locales resettled in the metropole, or writing from 'new metropolises' of Singapore, Hong Kong, Seoul, Jakarta, Tokyo, Beijing, and Sydney, 'conscientized' scholars in the First World, and expatriate Asians in the white nations of Europe and the United States, this scholarship is eroding the boundaries of area studies, properly speaking. Whether we are speaking of scholarship on gender inequality which Women's Federation scholars in Beijing produce in Chinese for national circulation, or studies produced in Tokyo and Seoul in English for international dissemination, or the steady translation of mainline US feminist and gender theory to a wide number of gender studies institutes throughout Asia, the full impact of localized scholarship on US-oriented area studies has yet to be registered. The trend toward globalized scholarship is exemplified in the work of the journal *Positions: East Asia Cultures Critique*, which publishes research that questions strict national divisions on which conventional area studies have rested and also injects the gender analytics into scholarship. The appearance of pan-Asian or regional cultural studies journals like *Inter-Asian Cultural Studies* (Taiwan), the *Asian Journal of Women's Studies* (Korea), and many others is also blurring the edges of area studies and area-oriented gender studies.

The effort to grasp the implications over the years 1970–2000 of re-regionalization (as well as the rise of flexible capital and gendered consumer markets) is producing significant lines of innovative global scholarship. The concepts of 'transnational Chinese capitalism' and 'flexible citizenship' allow Aihwa Ong, for instance, to propose the emergence of ethnicized capital flows which are not nationally grounded and which rest on the persistent powers of the state, opportunistically taking advantage of state forms (Ong, 1999). Modern Chinese transnationalism, its distinctive strategies of capital accumulation, and gender analytics are all being studied empirically. Specialists consider gender as a significant axis among other axes, such as ethnicity, nationality, sexuality, racialization, and caste status. A special issue of the journal *Positions: East Asia Cultures Critique* (1999) on 'Asian Transnationalisms' has highlighted these dynamics in relation to ethnicity and sexuality.

Advocates and critics of liberal globalization alike recognize the enlarged opportunities for public sexual expression opening up in the new metropolises of Pacific Asia. Sexualized and commodified styles of self-presentation open fresh possibilities for new social movements of minority social groups, such as self-styled queers (Ho, 1998). Minority sexual communities – gay, bisexual, nonprocreative heterosexual – exist in most of the new metropolises. The centrality of the gender analytics to scholarship about these communities and cultural criticism from within them are very clear in queer social, cultural, cinema, and theoretical studies which presume transnationality and track how sexual expression is gendered among specific groups of queers (see Manalansan, 1994; Hanawa, 1994). It is premature to consider how crosscurrents between queer criticism and a retrenched or renaturalized market heterosexuality will play out. One critic has shown (in a field study of young, heterosexual, urban, upwardly mobile, Chinese women) that claims to sexual pleasure have led to enriched lives. Yet, sexual rights have proved consistent with authoritarian forms of governmentality (Erwin, 2000).

Another avenue for innovation in gendered area studies of the re-regionalized Asia-Pacific has been the political economy of ethnic coding in intranational, transnational, and transborder contexts. Diasporic ethnicities such as the Hmong are trans-Asian minorities whose communities are now globalized. Ethnic and national coding have been significant to studies of minority service work in tourism and in gendered, often sexed, labor flows of subaltern national citizens from the Philippines into the boom economies of Taiwan, South China, and Hong Kong. Ethnographers and theorists are pursuing a combined transnational and ethnic focus that promises to clarify the political complexity of the new Asia-Pacific and its new social movements.

Conclusion

The analytics of gender offers increased penetration of markets as easily as it offers progressive scholars another significant index for gauging relative oppression and appropriately representing those who cannot represent themselves. Certainly advertising, cultural markets, and lifestyle expenditure in the ongoing consumer revolution refiguring the region are naturalizing heterosexual gender norms around anatomical sexual difference and the capacity to consume and produce what is appropriate to one's 'nature.' Increasingly feminist critique has taken up the problems endemic in consumer society as well as extending its traditional concern for poverty, antisexism, and freedom from reproductive tyranny and disease. Undoubtedly, scholarship will look increasingly at the conjugal pair, partly in order to queer commercial norms and partly to expose the political culture's reliance on a heterosexual mode of consumption.

Another task for gender analytics in Asia-Pacific area studies is to document the vast and increasing rifts that separate women in the same society, as well as the economic differentials between women and men affecting specific sectors. A related project will be to follow up on Li Xiaojiang's comment (2001) that the struggle for gender equality is a long historical struggle for all sectors and subgroups, classes, and class fragments, and should be studied as such. A further probable area of new research may be the political economy of pan-'Asianism' and the cultural production of women in transition in many of the liberalized state economies (Barlow, 1998). How the new social movements engaged in the Asia-Pacific (as elsewhere) proceed in the years 2000–10 may have some impact on how the gender analytics is employed in state policy making and that, in turn, will affect the problems taken up in academic venues.

Editor's Note

Gender dynamics in the East Asian societies have continued to evolve since Barlow's entry was initially published. Readers interested in this evolution will be well served by: Esther

Ngan-Ling Chow (2002); Marianne H. Marchand and Anne Sisson Runyan (2011); and Malcolm Warner (2013).

Abstract

Post–World War II studies of politics in East Asian nations have followed distinct patterns in the Cold War and post–Cold War periods. This article tracks and critiques major works published, mostly in English, in each period on politics in the People's Republic of China (hereafter China), the Republic of Korea (hereafter South Korea), the Democratic People's Republic of Korea (hereafter North Korea), and Japan. Studies of politics in Taiwan and Hong Kong are discussed in the Chinese sections and politics in North Korea in the Korean sections. An author is referred to as Chinese, Korean, Japanese, etc. on the basis of their surname, regardless of their present citizenship status or place of residence.

Studies of Politics in East Asia in the Cold War Period

This was a period when Japan was the center of media and academic attention in East Asia, first for its unprecedented position as a defeated, devastated, and occupied nation, then for its phoenixlike rise from the ashes of war as an extraordinarily fast-growing economy and an ultrastable polity. South Korean politics attracted nearly as much domestic and foreign media and academic attention during the period, but for a very different reason: it was extremely unstable, and often violent, under the rule of a succession of highly authoritarian governments. North Korea under Kim Il Sung's dictatorship was completely closed and inaccessible to foreign media and scholars, and non-Marxist social science did not exist within the nation. China was almost as inaccessible to foreigners until the early 1980s, a situation that allowed little objective and reliable research on its politics, especially on events played out at the upper levels of the national government.

Most studies of this period shared several interesting characteristics. They were, by and large, instigated or inspired by current headline-making political events, heavily influenced by the empiricist tradition of American political science, historical and descriptive rather than explicitly theory guided, and, until the late 1980s, almost exclusively focused on politics in one nation.

Studies of Japanese Politics

This was a period when Japan rose from the ruins left by a devastating war that had ended with the destruction of nearly all of its major cities by a half-year of relentless air raids, the last two by the first and last atomic bombs ever used in war. After a decade of dire economic hardships and political instability, the majority of which under the rule by Allied Occupation, the nation reemerged by the mid-1950s as one of the most dynamic and fast-growing economies and the most stable polities in the postwar world under seemingly permanent rule by a powerful conservative party formed in 1955, the Liberal Democratic Party (LDP). By the end of the 1960s, the nation had become the second largest national economy, next to the United States, and, while rocked from time to time by foreign policy disputes, corruption scandals, and external economic and political shocks, enjoyed sustained prosperity and political stability throughout the period. It commanded far more global media and scholarly attention and interest than either China or South Korea, not to mention North Korea, in this period.

Under the United States–led Allied Occupation for the first seven postwar years, Japan was also by far the most accessible nation to foreign, especially American, scholars to study during the early Cold War years, and beyond. In 1950, or about 2 years before the Allied Occupation of Japan ended, the University of Michigan Center for Japanese Studies set up a field station in Okayama Prefecture in central Japan for interdisciplinary research on changes under way in the nation's local society and politics. The 5-year work by the station (1950–55) resulted in the publication of *Village Japan* in 1959, a pioneering work that paved the way for a series of a half-dozen edited volumes published by Princeton University Press in the mid-1960s to the early 1970s under the general rubric of the modern and modernizing Japan. These works, along with other works by American, and a few British, scholars on the revision of the imperial Japanese constitution, purge of war criminals, land reform, and the 1960 US–Japan Security Treaty crisis inspired many studies of Japanese politics by Japanese scholars.

There was a substantial community of social scientists in prewar Japan, with its origins dating back to the late nineteenth century, and a group of them founded in 1948 the Japanese Political Science Association (JPSA) modeled on the American Political Science Association (APSA). Investigation of the causes and consequences of prewar and wartime Japanese 'fascism' was the main concern of its early members. Maruyama Masao's work (1963) exemplifies this line of investigation. Under the influence of American political science, however, the Japanese scholars' interest quickly expanded to include a wider range of themes and topics, such as the Japanese government bureaucracy, parliamentary and local elections, political parties, interest groups, public opinion, and social movements. The first major fruit of these efforts was a symposium volume published in 1958 under the title *Gendai nihon no seiji katei* (political processes in contemporary Japan).

The influence of American scholarship was particularly critical to works on Japanese elections and voting behavior. The founding of the Japanese Association of Electoral Studies in 1981 was inspired importantly by the survey-centered research that characterized electoral studies in the United States. The same was true of the studies of the LDP, the government

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10123-0

bureaucracy, and public policy making, which gained great popularity among scholars in both nations in the 1970s and 1980s. A major landmark in this line of work was the publication of Chalmer Johnson's book on the Japanese industrial and trade policy bureaucracy in 1982. This work triggered an international controversy on the nature and role of 'industrial policy' and the 'developmental state', and inspired a series of case studies on related subjects.

Studies of Korean Politics

For the greater part of the Cold War period, South Korea was, in sharp contrast with Japan, a nation under the rule of a succession of authoritarian and repressive governments led by, first, a fervently nationalist Christian 'Cold Warrior' with a Princeton doctorate in international law, Syngman Rhee (1948–60), followed by a succession of three army generals. Early in the period, the nation was devastated by the Korean War (1950–53) and, throughout the period, periodically rocked by military coups and massive, and often violent and bloody, anti-government revolts. Five constitutions and republics came and went one after another before a peaceful transition process began in the Sixth Republic at the end of the period. It was thus a nation viewed more with distrust and skepticism than with confidence and hope by most foreign scholars. The only bright spot in the generally dreary picture was the gradual, but accelerating, government-guided development of its economy beginning in the early 1960s.

Korea under the 35-year-long Japanese colonial rule and the authoritarian and isolationist regime that had preceded it had not nurtured a viable indigenous academic community. At the end of hostilities in the summer of 1945, however, the nation was placed under US trusteeship and remained closely allied with the US thereafter. As a result, information on South Korean politics was nearly as open and accessible to US-based scholars as information on Japanese politics during the postwar period. Under such circumstances, a Korean Political Science Association, modeled after the APSA like its Japanese counterpart, was founded in 1953 and, two decades later, in 1973, an Association of Korean Political Scientists in North America was formed by US-based scholars.

About halfway through this period, an American scholar published a landmark work on the cultural and institutional factors contributing to the strength of authoritarian centralism in South Korea (Henderson, 1968), followed by a series of works on problems of and prospects for a democratic transition, especially after the 1987 'democratic opening' and the birth of the Sixth Republic. At the end of the period, an American political economist published the first major work on the state-led industrialization of the South Korean economy under way (Amsden, 1989). More modest in number than English-language works on Japanese politics and political economy published in this period, these works nonetheless played a seminal role in the subsequent development of the study of South Korean politics and political economy.

By the late 1980s, a substantial number of studies in Korean (*Hanglu*) by Korean scholars began to be published in South Korea. Most were historical and normative accounts of Japanese colonial rule and postindependence politics under military rule and many were based, directly or indirectly, on Marxist or other radical theories, such as dependency theory. It was not until the 1990s that more American-style empirical political science became the main stream in the study of South Korean politics, or North Korean politics for that matter, by South Korean scholars.

Throughout the Cold War period, little factual information on politics in North Korea was available to scholars outside the nation and little serious research was done by them. A few exceptions were a comparative study of the foreign policy systems of North Korea and South Korea (Koh, 1984) and a political biography of Kim Il Sung (Suh, 1988), both by US-based Korean scholars.

Studies of Chinese Politics

For the better part of the Cold War period, mainland China was almost as inaccessible and factual information on its politics as unavailable to outsiders as North Korea. At the end of World War II, moreover, there were few social scientists anywhere in the world who were seriously interested in, much less knowledgeable about, modern Chinese politics. In the United States, Chinese politics was a serious concern only to a small number of historians, such as John King Fairbank and Karl A. Wittfogel. In Europe, scholarly interest in China was limited largely to a few British and Dutch philologists and historians, commonly known as 'sinologists'. Japan had a tradition of social science research on some aspects of contemporary Chinese society dating back to the 1930s. However, there was no systematic study of prewar or wartime Chinese politics by Japanese scholars of the period.

In the decades following the end of the war, scholarly, as well as general public, interest in Chinese politics grew rapidly, propelled by a series of headline-catching events: the onset of the Cold War, the Great Leap Forward (1958–61), the Cultural Revolution (1966–76), the initiation of multifaceted economic reforms (1978), and the Tiananmen Square incident (1989). In Japan, a group of about 50 scholars of Asian, mainly Chinese, studies founded in 1953 an interdisciplinary Japan Association for Asian Political and Economic Studies, renamed the Japan Association for Asian Studies a few years later.

The Cold War and the Cultural Revolution spawned intense ideological, and often explicitly partisan, debates among Chinese politics specialists around the world. These events, especially the Cultural Revolution, divided nearly all Japanese China specialists into friends and enemies of the Maoist regime and its policies. Even in Europe, where the tradition of nonpolitical sinologist approach was particularly strong, as sharp ideological divisions occurred among local China specialists as among their Japanese counterparts. This was also true of a segment of China specialists in the United States. A good portion of American scholarship, however, was deliberately nonideological and analytical. Some works applied concepts associated with modernization theory or elite and faction politics models. These works helped to lay conceptual foundations for studies of Chinese politics to follow in the late 1970s and 1980s, a period known for Deng Xiaoping's Reform regime.

Chinese political culture and elite and faction politics initially drew most attention among US-based scholars. However, the range of subjects and themes for investigation

gradually expanded to include local and minority politics, rural industrialization, special economic zones, and the military. Some scholars began to borrow terms and concepts from works on the contemporaneous political developments in Eastern Europe, such as civil society and public sphere. This practice paved the way for more explicit and systematic comparisons of political and economic reforms in China and Eastern Europe in the post–Cold War period. Many of the changes in American scholars' works were replicated in those of Japanese and European scholars. Above all, the heavily ideological and partisan overtones that characterized much of the work done in the heyday of the Cold War gradually dissipated toward the end of the period, as more and more foreign social scientists began not only to visit China for fieldwork, but also to collaborate with Chinese scholars.

The most significant development during this period was, however, the dramatic change in the way Chinese intellectuals thought about and discussed Chinese politics. This was an integral part of the sweeping transformation of the intellectual environment of Chinese society, especially in Beijing and other large cities. By the late 1980s, proreform, prodemocracy scholars, writers, and journalists began to form clubs, salons, and seminars and publish political journals and books (Gu, 1999). Translations of Western social science works by, for example, Max Weber, Robert Merton, Kenneth Arrow, Cyril Black, and Alex Inkeles, were published and apparently read fairly widely. While such intense intellectual and cultural fermentation was under way within China itself, US-based Chinese political scientists founded a Chinese Scholars of Political Science and International Studies in 1986, to be renamed the Association of Chinese Political Studies in 1995. The process of the democratic transition in China, however, was abruptly interrupted in 1989 by the Tiananmen Square incident. The event generated a spate of studies on the limitations of the incipient democratic polity and civil society that had emerged under the Reform regime. In the United States alone, some two dozen books were published on the subject in the decade immediately following the event.

The glare on the series of headline-grabbing events in mainland China left 'the other China', Taiwan, nearly totally ignored by scholars outside Taiwan itself during the Cold War period. The only notable exception was a modest amount of work on Taiwan's 'economic miracle'. It was not until the mid-1990s that serious scholarly work by foreign scholars on the reform and democratization in Taiwan began to appear in print.

Studies of East Asian Politics in the Post–Cold War Period

The post–Cold War period in East Asia saw dramatic status reversals between Japan and China and, to a lesser extent, South Korea. China's booming economy surpassed and began to overshadow Japan's, while its politics became increasingly open to direct observation and study by foreign media and scholars as travel restrictions were significantly loosened for both Chinese and foreigners. In the first decade of the new millennium, it was not significantly more difficult for a foreign scholar to visit China and study its politics than visit Japan or South Korea and study their politics. South Korea's economy, already a 'high-income developed economy' at the beginning of this period, continued to grow at a more moderate, but steady, pace, while the process of democratic transition and consolidation, also started at the end of the Cold War period, not only continued but accelerated in the new period. In sharp contrast with both countries, Japan alone experienced a seemingly endless recession and lifeless politics in the new period. It was no longer a particularly interesting, much less exciting, subject for the media to cover or a scholar to study.

The reversals of Japan's place on one hand and China's and South Korea's on the other have been accompanied by as starkly divergent trends in the number of their students studying at US universities. According to the United States Institute of International Education (IIE) statistics, the numbers of Chinese students studying at US universities increased fourfold from about 55 000 to 200 000 and South Korean students about 3.5 times from 41 000 to 72 000 between 2000 and 2012, while the number of Japanese students decreased by 60% from 47 000 to 20 000 over the same period. There were thus more than 20 times as many Chinese and 9 times as many South Korean students as Japanese students enrolled at US universities in 2012. On the basis of incomplete data available in reports published by IIE and East Asian governments, we may estimate that about 900 Chinese, 200 South Korean, and 40 Japanese students were enrolled in political science doctoral programs in any recent year.

It is also well known that, upon completion of their study at US universities, the majority of Chinese and Korean students stay on and settle down in the United States, whereas nearly all Japanese students return to Japan. Those hundreds of Chinese and South Korean political science PhDs who continue to live and work in the United States, often as university faculty members, tend to publish their studies in English, adding to the literature accessible to scholars around the world, whereas the few dozen Japanese PhDs and doctoral candidates who return to Japan tend to publish, if they do, only in Japanese, making it virtually impossible for most foreign scholars to access them.

As in the Cold War period, most studies of politics in East Asia in the post–Cold War period were 'event-led' descriptive works. The seminal influence of American political science remained perceptible in most works published in this period. Unlike in the preceding period, however, single-nation studies no longer dominated the field and intraregional and extraregional comparative studies of a variety of political phenomena and themes became increasingly commonplace.

Studies of Chinese Politics

Riding the sustained economic boom triggered by Deng's reforms in the late 1970s, China surpassed and replaced Japan as the world's most dynamic and second largest national economy in the post–Cold War period. At the same time, the marketization of the economy and, to a lesser extent, liberalization of political control gave rise and increasingly drew public and media attention to a number of new political issues, such as the increasing income and wealth inequalities, deterioration of the environment, widespread corruption among politicians, bureaucrats, and even the military, and increasingly vocal grievances of several minority groups, such as Tibetans, Uighurs, and Mongols, against the dominant majority Han

Chinese. Many of these issues then became the main subjects and themes for scholars, both within and outside China, to research and write about, as well as for Chinese governments and policymakers at all levels to tackle and try to resolve, with varying degrees of success.

In an increasingly open China of the post–Cold War period, foreign scholars had and availed themselves of opportunities to visit and engage in fieldwork with little difficulty. At the same time, Chinese governments at all levels began to publish a substantial amount of factual and detailed information and data on a widening range of domestic politics and policy issues, especially after an ambitious program of across-the-board administrative reforms was launched in 1998. There was also a corresponding rise in the amount of factual information, including results of sophisticated public opinion surveys, and editorial commentary on domestic and foreign policy issues purveyed by increasingly independent and articulate Chinese national, provincial, and local print, and to a lesser extent electronic, media. Aided by these developments, research and publications on a widening range of subjects became substantially more data-rich and analytically sophisticated, especially on local and minority politics and the military and security policy.

The thematic focus of domestic and foreign media and academic attention in this period was the evolving state and prospects of the 'Reform regime' and democratic transition. More than a dozen books in English on related subjects were published by US-based scholars alone in the first two decades of the period. Integral to this body of research was a smaller but growing literature on the role of public opinion and the mass media. Nearly as many books and articles were published on the 'marketization' of the Chinese economy, a subject closely related to the political reform and democratic transition.

A conspicuous and intriguing aspect of the study of Chinese politics in the post-Cold War was the growing presence of Chinese scholars based outside China, predominantly in the United States, and publishing the results of their research in English for an international audience. They account for roughly half of the authors of the relevant works reviewed for this article. This resulted partly from the rise of a generation of Chinese scholars born abroad in English-speaking nations, especially the United States, and partly, as suggested already, from the settlement in such nations of a substantial number of Chinese graduate students from China upon completion of their studies at US universities. The latter phenomenon reflects the state of political science, especially the study of Chinese politics, at Chinese universities and research institutions in particular.

With a view to making their institutions of higher education 'first-rate' by world standards, China has made enormous investments since the early 1990s in the construction of new universities, renovation and expansion of old ones, and improvement of the quality of both teaching and research conducted at all universities. Today, most of China's leading universities, such as Peking, Qinghua, and Fudan, offer political science as a field of specialization both at the undergraduate and graduate levels.

These developments, however, have not prevented a huge outflow of students to foreign, especially US, universities, nor many students' permanent settlement abroad. According to most estimates, only a minority of the Chinese students enrolled at US universities in recent years returned to China after graduation and virtually none of those whose study abroad was privately funded did so. For many political science students, this was probably due, at least partly, to the state and environment of higher education in China, where the tradition of Marxist political economy still remains strong and the most important requirement for appointment to a faculty position is said to be not a doctorate but membership of the Chinese Communist Party. According to surveys conducted by the IIE, virtually all East Asian students in the United States were attracted by 'new ways of thinking' they found at US universities.

An unintended consequence of this phenomenon was, as noted already, a tangible increase in the number of Chinese scholars of Chinese politics based abroad and publishing the results of their research in English. While China-based scholars published increasingly sophisticated works in Chinese, the English-language literature remained the main repository of advanced scholarship in the field. In this respect, the state of the study of Chinese politics was somewhat similar to the case of South Korean politics, but sharply contrasted with that of Japanese politics.

Politics in Taiwan continued to be largely ignored by foreign scholars in this period, but a few noteworthy works were published in English on its party politics and political economy (Fell, 2005; Clark and Tan, 2012).

Studies of Korean Politics

In South Korea, the democratic transition initiated toward the end of the Cold War period moved forward at a breathtaking speed. Free and fair presidential elections fought between civilian candidates, mostly of moderate or liberal persuasions, became routine, and so did free and competitive national and local legislative assembly elections. Civil society, effectively suppressed and silenced under the Japanese colonial rule and the postwar Korean authoritarian regime, resurfaced and began to play a key role in the accelerating process of democratic transition and consolidation. In the 2000 National Assembly election, a coalition of 460 or so civic organizations launched a nonpartisan 'throw out the rascals' campaign against corrupt candidates. The presidential election the next year elected an activist left-wing human rights lawyer, a development unthinkable only a decade before.

The sustained growth of South Korea's economy since the 1960s continued and, by the beginning of this period, the nation had grown into a 'high-income developed country' and a member of the Organization of Economic Cooperation and Development, as well as the United Nations. It was hit hard by the 1997 Asian financial crisis, to the extent that it was placed under the International Monetary Fund's temporary trusteeship, but recovered from the shock and was back on track within a few years. As in China in this period and Japan in the previous period, however, the rapid economic growth was accompanied by the proliferation of corruption scandals involving prominent politicians and bureaucrats and sensational media reports on them. In 2001, two of President Kim Dae-jung's sons were arrested on bribery charges.

Throughout this period, democratic transition remained the central thematic concern for most Korean politics scholars within and outside the nation with increasing attention paid to the role of civil society. The political economy was another popular subject of academic investigation and discussion. Amsden's pioneering work published at the end of the Cold War period was now followed by several others, most of them developing or modifying one or more of Amsden's arguments and conclusions in light of the 1997 financial crisis. The scope of the investigation and discussion extended also to other related issues, such as the politics of social welfare, environmental protection, and public health.

As in the case of the study of Chinese politics, a notable development in the study of South Korean politics in this period was the emergence of a substantial number of Korean specialists of Korean politics trained, directly or indirectly, in the tradition of American political science. According to the results of a 1995 Korean Association of International Studies survey of its 1300 or so members, nearly half of them had earned their doctorates at US universities and about one-third at Korean universities. A 2011 Korean Research Foundation survey of 2050 or so political science faculty members at South Korean universities, however, found a little less than one-quarter of them with doctorates earned at US universities, a little over half with degrees earned at Korean universities, and the remaining quarter with degrees from universities in other foreign countries, predominantly in Europe. This suggests a substantial decline in the proportion of US-trained political scientists and a corresponding increase in that of homegrown political scientists teaching at South Korean universities in recent years. The significance of this change, however, is not as great as it may appear, because today's South Korean universities in general and their graduate programs in particular are closely modeled on and replicate their US counterparts, especially with respect to the requirements for the attainment of a doctorate. It should be also noted that, as in the United States, all applicants for a full-time faculty position at a South Korean university are required to have a doctorate at the time of application.

An important corollary of this circumstance is the impressive presence of Korean scholars, whether born in Korea or abroad, among the authors of the most widely read recent works in English on South Korean politics. Like their Chinese counterparts, they account for about half of such authors who have published in this period, potentially sharing the fruits of their research and ideas with a much larger number of fellow scholars around the world than they would be if they published only in *Hanglu*.

Scholars' interest, as well as governments' and journalists', in North Korea substantially increased in this period and a fair number of scholarly books and articles in English have been published on the viability of the ruling Kim dynasty after the death of its founder, Kim Il Sung, in 1994, the current state of and future prospects for its nuclear weapons program, and North–South relations and the prospects of reunification. The nation, however, remained as closed to and hidden from outsides' scrutiny as during the Cold War period and research on any aspect of its domestic affairs, but especially politics, continued to be, as the author of a book review commented, a practice "reminiscent of medieval scholasticism or ancient Chinese oracle-bone divining" (C.K. Armstrong 1999 in Gu, 1999: 224).

Studies of Japanese Politics

The end of the Cold War period coincided with the end of the widely reported and admired performance of the postwar Japanese economy. Its annual growth rate, which had registered a stunning 9.1% annual average in the 1956–73 period and a more modest but still respectable 4.1% in the 1974–89 period, fell to a 1% average over the next two decades. Meanwhile, the nation's population steadily aged, the under-15 cohort shrinking from about 20 to 13% of the total and the over-65 cohort swelling from about 10 to 23% between 1990 and 2010. This rapid 'graying' of the population, a combined effect of a falling birthrate and rising longevity, led the Japanese government to increase social welfare and health-care spending, without raising taxes in the face of voters' dogged opposition, and allow the government debt to reach 200% of GDP, by far the highest in the world.

This was also a period when the superstable one-party rule by the LDP was replaced by an extremely unstable two-party-dominant system, a result of the LDP's loss of sustained public support due to recurrent corruption scandals and the economic downturn. In the first few years of the period, the LDP suffered a series of defections by affiliated Diet (parliament) members concerned about the electoral fallouts of the corruption scandals, who formed a rival conservative party, to be later named the Democratic Party of Japan. The new conservative party, in cooperation with other opposition parties, defeated the LDP in the 1993 House of Representatives general election, bringing the one-party regime to an end. This ushered in a period characterized by a series of annual government turnovers, each government leaving all the pressing economic and social problems facing the nation not only unresolved but even worsened.

Japan in the post–Cold War period has therefore been neither a model high-growth economy nor a unique 'uncommon democracy' (Pempel, 1990) worth as intense media and academic curiosity and attention as in the preceding period, except when the nation was hit by a disastrous earthquake and tsunami in the spring of 2011. The focus of foreign media and academic interest shifted increasingly to the far more dynamic and interesting China and South Korea. A significant number of sophisticated studies have nonetheless been published on wide-ranging subjects: elections and voting behavior, parties and party politics, interest groups, the bureaucracy and policy making, environmental protection, national security policy, and the roles and power of the media, civil society, ethnic minorities, and women. The widely reported administrative reforms, especially the privatization of the postal services, undertaken by the last durable and successful LDP government led by a maverick politician, Koizumi Junichiro, during the first half of the 2000s, led to the publication of a series of books and articles on the subject by scholars inside and outside Japan.

In striking contrast with contemporaneous works on Chinese and South Korean politics, an overwhelming majority of studies in Japanese politics published in English in this period were authored by foreign scholars, predominantly

Americans. Japanese authors contributed only about one-third of the 40 so notable English-language books published in the first two decades, including several coauthored by one or more Japanese and foreign scholars. This does not mean, however, few Japanese scholars study and write on Japanese politics, but that most Japanese scholars write and publish not in English but in Japanese. This situation corresponds with the fact that, as already pointed out, a relatively small and steadily diminishing number of Japanese graduate students attend foreign, especially US, universities, a phenomenon attributable mainly to the availability of a much easier and inexpensive alternative to earn university degrees, including doctorates, at Japanese universities.

Until a few decades ago, Japanese universities, steeped in European educational tradition, regarded and treated a doctorate as an honor to be conferred on a senior scholar in recognition of an extraordinary record of accomplishments, such as the publication of multiple important books or articles, rather than just the completion of an advanced graduate course and an accepted dissertation. At the same time, professorship at a Japanese university did not require a graduate degree, much less a doctorate. The practice, however, began to change drastically in the early 1990s and today doctorates are increasingly required for appointment to regular faculty positions at most Japanese universities and granted by numerous Japanese universities. More than 500 of them offer doctorates in the social sciences.

Nonetheless, a substantial number of political science faculty members at Japanese universities still do not hold a doctorate. In August 2012, a little over half of the about 1000 JPSA members currently teaching at Japanese universities held doctorates, a little over one-third master's, nearly 5% bachelor's, and the remaining 10% were unknown. Of those doctorate holders, nearly 80% had earned their degrees at Japanese universities and about 10% each at US and other foreign universities. An important reason for Japanese students' preference for Japanese doctorates is the flexibility, or laxity, allowed by most Japanese universities to satisfy the requirements for the degree: one can either enroll in a doctoral program at a particular university and complete both a course of classes and acceptable dissertation for a 'course doctorate' or complete a course at one university, then later write a dissertation and submit it either to the same university or any other degree-granting university for a 'thesis doctorate'. About 70% of those who held Japanese doctorates among the JPSA members in 2012 were 'course doctors', 20% were 'thesis doctors', and 10% were unknown. The hiring practice of most potential Japanese employers, including the nation's most prestigious universities, to give preference to holders of degrees from Japanese universities over those with degrees from foreign universities further discourages Japanese students from going abroad for a degree at considerable financial costs and, in most cases, with a substantial language handicap.

Not surprisingly, those who attend only Japanese universities tend to write and publish only in Japanese and nearly all do so. There are in Japan about a dozen major trade book publishers, half-dozen university presses, and several independent political science journals that publish their works, mostly subject to perfunctory manuscript reviews. In principle, these works are accessible to anybody who reads Japanese. The majority of Japanese professors' works, however, are published in the nonrefereed in-house periodicals of their own departments or schools, circulation of which is typically very limited and largely inaccessible to outsiders, especially to foreign scholars.

These circumstances tend to increasingly isolate and insulate Japanese political scientists in general and Japanese politics specialists in particular from the international community of scholars and limit opportunities for free give-and-take and collaboration between them. In the larger scheme of things, then, this trend of 'indigenization' may be the most important development in the study of Japanese politics in the post–Cold War period, which sets it apart from the evolving states of studies of Chinese and Korean politics.

Intraregional and Extraregional Comparative Studies

While the majority of studies of East Asian politics published in English in the post–Cold War period were single-nation studies, a modest number of works investigating certain political phenomena, such as Confucianism and democratization and political underpinnings of economic development or debacle, in cross-national or cross-regional comparative perspective, have emerged. These include studies of political and economic reforms and social welfare policies in South Korea and Taiwan, reunification issues between mainland China and Taiwan on one hand and South and North Koreas on the other, 'crony capitalism' in South Korea and the Philippines, political and economic reforms and transitions in China and Hungary, political power of business corporations in Japan and France, etc.

In the most ambitious studies of this type, region-wide political phenomena or developments in East Asia are compared with those in another region or regions. Stephen Haggard and his colleagues' work on the political economy of democratic transitions in East Asia and Latin America is an outstanding example of this type of studies (Haggard and Kaufman, 2008). McGuire's on the complex relationships between the levels of wealth, the quality of the welfare state, and the state of democracy in a dozen nations in the same two regions is another (McGuire, 2010).

Most of the comparative studies published in English in this period were descriptive case studies, like their predecessors of the Cold War period. Some, however, employed one or another theoretical model, or at least perspective. These include the use of a sociological evolutionary model in a study of Chinese foreign policy, the two-level games model in a study of Japanese–United States trade negotiations, network analysis in a study of Japan's relations with its Asian neighbors, and so on. Rational choice theory was used in a few studies of Japanese and South Korean politics.

The studies of East Asian politics in the post–Cold War period have thus become far more thematically and methodologically diversified than in the Cold War period.

Eastern European Studies: Culture

Michael D Kennedy, Brown University, Providence, RI, USA

This article is a revision of the previous edition article by M.D. Kennedy, volume 6, pp. 3979–3984, © 2001, Elsevier Ltd.

Abstract

The Cold War moved an American knowledge establishment to build area studies. Its East European focus built on Enlightenment notions of a contradictory place neither Orient nor Western. This combination of proximity and 'backwardness' shaped much of Eastern European Studies, but the region's diversity worked against the cultivation of area studies from within. The nation, however, has shaped other cultural studies and remains an object of study itself, elevated by the region's distinctive experience with communist rule. With communism's end, more culturally articulate methodologies prosper as they refashion historical understandings as well as meet more contemporary challenges of translation around transnational cultural politics.

Culture can be treated as a distinct object of study. For instance, literature and art are usually understood as expressions of 'high culture,' while the economy is typically studied as something apart from culture. Culture also is used to differentiate groups. Nations are not only political categories, but they are distinguished by language, ways of life, and interpretations of the past. Some argue that to explain social life at all, one must understand meanings in everyday life, or the culture of a place and time. Finally, culture is fundamental in social inquiry itself. It is embedded in the process through which the objects of our inquiry are constituted. All of these meanings of culture inform this alteration of an entry originally composed at century's end.

This revision again uses the final sense of culture referenced above to shape its overall architecture, but, given constraints on numbers of references, it omits original citations to allow for more recent work to be identified. To recognize some of the most important recent work, I also have drawn upon suggestions from a number of colleagues whose identities remain anonymous, as I have promised them.

The notion of 'Eastern European Studies' should be understood as a regional theme in the more general enterprise called 'area studies,' that interdisciplinary study of a region's languages, cultures, histories, and institutions (Wiley and Glew, 2010). This particular form of scholarship achieved great prominence in the USA during the Cold War, during which a new linkage between Western geopolitics and scholarship was cultivated. The American government sought expertise about other parts of the world in order to aid its struggle against communism's spread. Consequently, it subsidized research and training in area studies across the world's regions.

Combining Western geopolitical aims with scholarly work was relatively more compatible in studies of Eastern Europe and the Soviet Union than of other world regions. During and after World War II, the Soviet Union expanded its borders to include Estonia, Latvia, Lithuania, and Western Ukraine and Belarus, while communists took power in other parts of Eastern Europe – East Germany, Poland, Hungary, Czechoslovakia, Romania, Bulgaria, Yugoslavia, and Albania. Many political émigrés from these countries could be found among the West's experts in Eastern European Studies. Despite the political associations of exile and state sponsorship, Eastern European Studies enjoyed relative autonomy and scholarly growth through its location within various disciplines and universities. After communism's collapse throughout the region, Eastern European Studies no longer faces such obvious political implication. It does, however, face a challenge of coherence and other problems associated with culture's place in disciplinary practices.

Eastern Europe as Cultural Category

It is unlikely that Eastern Europe would be invented as a category if the world in which I write defined our geographical scholarly imagination. While East European nations are not so prominent as France and Germany in the status hierarchies and power relations of the European Union, the EU's formal organization and rights diminish the cultural sense of speaking in terms of Eastern Europe, at least with regard to nations presently within it (Böröcz, 2006; Kennedy, 2012). However, there are powerful historical foundations for its abiding reference.

Eastern European Studies has its antecedents in various forms of civilizational study, most notably 'Orientalism.' Like Orientalism, area studies expertise tends to be organized through networks of knowledge production grounded outside the region. While the Cold War inspired American area studies projects, an East European focus could build on an earlier West European invention. During the Enlightenment, West Europeans understood this region, then including Russia, as neither Orient nor Western, occasionally recognizable but also distant despite a number of overlapping cultural flows.

This tension between Western proximity and 'backwardness' shaped much of Eastern European Studies. One enduring debate asks whether Eastern Europe's indigenous social relations or its trade relations explain its economic underdevelopment over the last 400 years. Despite its economic trajectory, east European art, music, architecture, and literature have thrived, leading some to identify modernity's disarticulation as a regional distinction. These accomplishments lead others to argue that Europe itself should be understood as much from its east and especially its center as from its west.

Eastern European Studies has not only been cultivated in the West. For instance, the Soviet Union had its own complement of area studies. Eastern Europe was particularly important in this array given the role post-World War II Eastern Europe played, until *perestroika*, as a *cordon sanitaire*. Within Eastern Europe, however, the region's area study is not well developed; the region is rarely articulated as a category of cultural imagination. East European diversity has invited much finer breakdowns.

Most significantly, the region's imperial heritage is diverse – with the Ottoman, Habsburg, Russian, and Prussian empires shaping the region's long nineteenth century, with enduring effect. The 'Balkans,' especially those territories of the former Ottoman Empire in Southeastern Europe, have remained an important regional category throughout the twentieth century; with war in the 1990s, the term gained new cultural power. Those from the Westernmost parts of Eastern Europe also took the area's diverse imperial legacy as a starting point for their contemporary critique of Soviet domination, arguing that communism ill suited East *Central* Europe with its more developed civil societies. Some resisted Cold War categories altogether and argued that East Central Europe's boundaries should move into Soviet space, to include the lands of the fifteenth- and sixteenth-century Polish–Lithuanian Commonwealth. Others even organize scholarly collaborations on those terms.

There is no simple cumulation of scholarly competencies in Eastern European Studies. There has been no regionally hegemonic language, like Russian was in the Soviet Union. Depending on the boundaries one invokes, and the time one imagines, different languages have been more and less dominant and numerous. For example, in 1900, Germans, Poles, and Ukrainians may have been the largest ethnolinguistic groups in East Central Europe, but Romanians, Hungarians, Czechs, Belorussians, Serbs, Greeks, Bulgarians, Croats, Slovaks, Lithuanians, Slovenes, Albanians, Macedonians, Bosnian Muslims, and Montenegrins were all dominant in particular places across the region. Beyond these groups who then had, or who would eventually have, East European states in their name, there were significant numbers of Jews, Turks, Gypsies/Rom, Italians, Carpatho-Rusyns, Szekelys, Friulians, Armenians, and other ethnolinguistic groups.

There also is no principal religious tradition in Eastern Europe, whose status Islam occupies in the definition of Middle Eastern and North African studies. Islamic and Orthodox, Roman Catholic, and Protestant Christian religions dominate various parts of the regional religious landscape. Judaism was demographically and culturally significant before the Holocaust, and even after genocide, Judaism remains critical to understanding the region's cultural politics. Thus, while Eastern Europe is itself a profoundly important cultural category, it is not based on the region's cultural homogeneity. Eastern European Studies is, however, profoundly shaped by the culture of nations and nationalism.

The Significance of the Nation

Cultural analysis in Eastern European Studies draws upon an indigenous scholarship, but one organized through national and past imperial fields rather than across the region's whole. For instance, Polish sociologies of the intelligentsia, both before and after World War II, had the nation, and the multinational republic out of which it grew, as their field of reference. Hungarian ethnographies of the countryside, while foundational for Western anthropology's study of Transylvania and elsewhere, were focused on the making of the Hungarian nation and its relation to empire. Musicology or literary criticism also has been organized within national and imperial fields, around leading figures like Béla Bartók or Witold Gombrowicz, whose complicated expressions of their identifications through music and literature form leitmotifs of their cultural interpretation. Consequently, the nation is one of the region's most important cultural formations. It shapes other cultural studies and is an object of study itself.

Studies of the nation are themselves framed within larger cultural formations. Many studies of the nation in Eastern Europe are set up within a narrative of civilizational distinctions. For instance, national historiographies tend to depict the Ottoman Empire's expansion through the 1600s and its retreat from the Balkans during the nineteenth and beginning of the twentieth century in terms of a nationally articulated contest between Islam and Christianity, on which more recent stories of civilizational clash draw. Romanian national historiographies identify their civilizational alternatives with Western and more autochthonous traditions. Estonian social science around ethnicity can portray a 'civilizational' difference between the West and Russia.

In contrast to those who demonstrate enduring cultural oppositions, others have emphasized the *process* of establishing national identity and difference, asking, for example, how intellectuals articulate nations. These recurring questions in national stories tend to differ by place. Those who focus on 'historic' nations and nations that had to '(re)awaken' have different emphases. The latter tend to ask how peoples come to recognize themselves as nations and how they mobilize to realize political ambitions including the formation of nation-states out of imperial states. Those who focus on historical nations are more influenced by narratives of loss, whether of sovereignty, territory, or tolerance.

Nationalism and its study are not limited to Eastern Europe, but the region was foundational, given the ways in which scholars used this region to highlight the original categorical variants of civic and ethnic nations. The last decade's emphasis on the discursive construction of nations implicated in various fields of practice has made such gross distinctions of nationalism fade, at least in the scholarly domain. It remains prominent in political discourse if with new accents.

Discourses around corruption, for example, have become more commonly used in defining less virtuous nations, aided and abetted by social scientific methods creating indices of transparency and trustworthiness in business, politics, and everyday life (Ledeneva forthcoming). Bulgaria and Romania, while full members of the European Union, have been indicted for this lack; those aspiring to accession in the European Union face even stiffer criticisms for such deficit, whose likelihood is made even greater by war's aftermath.

The Wars of Yugoslav Succession and their abiding effects continue to shape nations and nationalisms and their identifications from without. Superficial and interested actors can

elaborate accounts of 'ancient hatreds' to structure practice around mythologically perpetual animosities. More culturally articulate scholarship moves to explain how memories of oppression by others, rekindled by polyvalent symbols, became the cultural stock for civil societies' and political networks' mobilizations to hate and violence.

As national security comes to be more established, and with more international collaborations and methodological diversity influencing studies of the nation, contests over the meaning of the nation, whether through symbols and events in everyday life (Zubrzycki, 2006; DiLellio and Sievens-Schwander, 2006; Brubaker et al., 2008), or in their historical constitution with other nations' imperialisms (Pula, 2008), have become far more significant. It is also critical to consider under communist rule and in its transition culture sequel.

Culture, Civil Society, and Transition

Communist rule encouraged many nationally articulated scholars to consider culture to be autonomous from the system forced upon them. Socialist realism in the cultural sphere, while often accommodated, was often seen as an imposition against which more authentic cultural expressions sought release. These expressions could be national in form, or evaluated with various aesthetics in mind. Indeed, while communism's political censorship certainly constrained cultural expression, it also made artistic expression broadly valued and relatively independent of culture's commodification. At the same time, that expression could be seen as part of a broader struggle for freedom for which the nation was a primary container and vehicle, manifest in the punctuations of communism's systemic crises, in 1956, 1968, 1980, and 1989 most obviously.

The Hungarian Revolution of 1956, the Prague Spring of 1968, the Solidarity movement of 1980–81, and the end to communist rule throughout most of the region in 1989 all implied a mismatch between the nation and communist rule. Studies of political culture were frequently organized to explain the conditions under which the political cultures of some nations would or would not resonate with communist political culture. More recent studies tend to break down the assumption of opposition between nationalism and communism and rather study how opposition and authorities construct the nation in their own terms. Not every nation managed to develop easily imagined dichotomies of 'us' and 'them' however. The discourse of civil society was critical to that formation.

That discourse found modes of expression, and even optimism, in various cultural products and forms of social organization. Civil society's culture was argued to be tolerant, pluralist, and progressive. Just as studies of the nation have struggled to move beyond their political instrumentalization, so too have engagements of civil society. While it was politically fortuitous to assume civil society as a harmonious blend of ideology, social organization, and vehicle of liberation in opposition to communist rule, its formation after communism is radically different. The very spaces opened up in civil society's flourish could also produce nationalist expressions that threatened others and even lead to war. But it also led to much more diverse accounts of social identity and relations after communism, initially within a new hegemonic frame of transition.

Communism's end offered peoples new opportunities to redefine their nation, and this invited substantial scholarly engagement. These transformations were apparent already in 1988, when for instance the polysemy of Béla Bartók was played out in the last summer of communist monopolistic rule in Hungary (Gal, 1991). Some scholars shaped claims to national distinction with their own expertise, clarifying the ways in which proximate languages were related to one another and could distinguish nations, leading others, further removed, to explain the complexities and sources of these arguments. Some utilized less culturally reflexive approaches like rational choice or game theory, but the cultural field and historical legacies of places and peoples continued to shape scholarly approaches to national identification. While the nation demanded some attention to historical legacies and cultural formations, other subjects seemed to move without cultural reference.

In the first years after communism's collapse, most studies of transition to markets and democracy were rather formal and structural, as more and more scholars without contextual expertise identified Eastern Europe as the natural laboratory for testing their generalizing theories. This led to significant debate, especially in political science, about the relative value of area studies. Much of the contest hinged upon how much one needed to know about culture and history in order to produce a good explanation, but it did not attend to the global cultural formation of transition itself (Kennedy, 2002) and to how the 'normal' was itself an ideological element structuring change and contest (Eglitis, 2002). Of course methodology also matters in this variable attention.

Ethnographies of transition were more likely to question the guiding concepts of transition, especially by noting the hermeneutic gap between transition's key concepts and their everyday meaning (Berdahl et al., 2000; Ghodsee, 2011). For instance, such inquiries help us appreciate the difficulty of distinguishing private from public ownership and the meanings of property itself (Verdery, 2003). Sometimes ethnographies even challenged the framework in which transition is envisioned, notably in the kinds of capitalism actually being constituted.

A similar range of questions has emerged around gender studies. As in most transition studies, some gender analysts have kept culture at a distance. By treating gender more as a variable – asking, for instance, whether women's employment chances have been disproportionately hurt by economic transition – cultural analysis is less obviously necessary. But when gender serves as a lens for interpreting social change, gender studies engage profound cross-cultural questions. For instance, terrific debates have occurred over the measure of cultural imperialism involved in Western feminism's categories and modes of inquiry with regard to Eastern Europe. Indeed, some have argued that transition has helped constitute new gender identities differentiated by the profound inequalities made by distinctive logics of market transition (Weiner, 2007). Beyond object and lens, gender also has become one of the most powerful vehicles for developing collaborations across the region, for example, around citizenship (Lukić et al., 2006) and visual culture (Pejic, 2010).

Cultural Formations after Postcommunism

As a field of inquiry, Eastern European Studies has been organized through culturally constituted geopolitical categories whose sense has changed profoundly. During the Cold War, questions of fit between particular nations and communist rule seemed to drive Eastern European Studies. After communism's collapse, the field was reconstituted around questions of transition and nationalism's threat. While the logic of transition culture continues to influence candidate countries aspiring to EU membership, cultural social science has moved well beyond its hegemonic frame, not least for the transformations wrought by European Union enlargement and the inequalities borne within it.

One of the best examples of this shift can be found in Gille's (2007) analysis of the Hungarian waste economy's movement from an emphasis on 'reuse' during early socialism toward waste disposal in its end and after. In particular, the European Union's provision of model legislation, technology, investments, and even waste created a new landscape in Hungary filled with more landfills, incinerators to deal with them, and the environment resulting from it. While illustrative of the critical turn, work like Gille's also illustrates Eastern European Studies' increasingly broad range and methodological diversity.

On the one hand, open borders to scientific collaboration enabled social scientists without area expertise to work with indigenous scholars to produce important findings, bracketing culture as extraneous to the scholarly enterprise in ways that area studies could never manage. More open borders have also meant, however, greater room for life histories, ethnographies, and other direct qualitative fieldwork, and more intimate portraits of everyday life and assessments of its fit with the larger frameworks guiding global visions of Eastern Europe in its historical trajectories. More open research opportunities have, in effect, enabled a more critical cultural social science. This is especially evident in rethinking communist rule itself.

Transition culture demanded that socialism be left behind. Even as populations age and direct experience with the system fades, more scholars are examining how various genres of memory reflect different subjectivities, power relations, and contests under communist rule (Todorova, 2010) with artists among the most critical in that endeavor (Von Oswald et al., 2009). In particular, explorations of communist era monumentalities, and their relationship to subsequent cultural politics, have become an increasingly prominent part of East European cultural studies (James, 2005).

At the same time that memories of the system are being analyzed, the actual processes of transformation, and their implication in cultural systems and practices, are being explored with increasing analytical and theoretical rigor. Some consider how the material culture of the system (Fehervary, 2009) or its media (Bren, 2010) allows us to recognize its political logic. Others have revisited the system's founding moments; for example, Kligman and Verdery (2011) help us understand better not only how classes were remade through collectivization but also how in the process socialist society was 'personalized' and mistrust systematized. Still others have explored how the system actually collapsed; for example, Glaeser (2011) has proposed that one reason socialism collapsed was because the authorities' understanding failed; it was based on circular validations preventing their recognition of the system's dynamics, which in turn prevented them from crafting an appropriate response to the opposition's challenge.

While East European Studies thus still cohere by understanding the system that made such a regional identification compelling, some of the most exciting cultural social science in East European Studies resonates far beyond the region's historiography. For instance, Keith Brown (2013) not only helps us to appreciate the historical foundations of the Macedonian Revolutionary Organization, but also offers new conceptual tools for rethinking the relationship between terrorism and flows of labor, guns, and of revolutionary strategies and of imagined communities beyond nation but residing in terminal communities of another constructed sort. It is also apparent in Kubik and Lynch's (2013) volume refashioning East European Studies through the elevation of vernacular knowledge in theory, evidence, and practice around the articulation of hegemony, injustice, and social movements.

As part of a new post-Cold War conception, such work invites comparisons to the postcolonial, as Forrester et al. (2004) and Chari and Verdery (2009) propose. Indeed, recent scholarship in Kosova suggests that scholars working in the region could offer new critical frameworks through which not only contests over socialisms' past and wars' outcomes but around ongoing internationalist interventions refigure conceptions of gendered and emancipatory publics (Luci and Gusia, 2014). Indeed, a strong case might be made that in an era where publics become thin and passive, feminist art interventions offer a means, here in Poland, to stimulate greater reflexivity in public discourse (Matynia, 2005). And it might even go further.

Larson's (2013) ethnography of critical thinking in Slovakia suggests that we are better served to consider the ways in which even such noble pursuits as civic education build into their cultural politics other modes of dogmatic thinking. In this sense, while the iconic captive mind of the communist era is a thing to be resisted, its opposite is not so easy to cultivate, regardless of location. Eastern Europe makes that quite clear.

Abstract

This article is a brief survey of the current state of and trends in academic historical scholarship on Eastern Europe, mainly in North America, but also in Europe. It presents several traditional methods of defining Eastern Europe, discusses main features of its historiography and some of its recent research directions. The article offers both a chronological and thematic narratives concerning the field's origins, its major developments and shifts as well as a reference guide for further research and reading.

The field of Eastern European historical scholarship has undergone dramatic changes since the collapse of communist regimes in 1989. Eastern Europe as a distinct geopolitical region has never been more sharply delineated than between the late 1940s and 1989, when its primary reference was essentially synonymous with the term 'Soviet Block.' In the West, 'Eastern Europe' as an intellectual concept had its origins in the Enlightenment vision of the world; it referred to a transitory space between the civilized 'West' and the exotic 'Orient' (Wolff, 1994). As a scholarly discipline it began to emerge only in the interwar period – it dealt with the newly organized space that appeared on the map as a result of the fall of four empires: Austro-Hungarian, German, Ottoman, and Russian. It was the Cold War and its geopolitical pressures, however, that led to the emergence of 'Eastern European studies' as an institution well-established in the academic world. Many historians of the region were émigrés and – as they were collectively labeled in the West – 'dissidents,' who through their research, writing, teaching, and not infrequently – government advising, were involved in the process of 'liberating' Eastern Europe from the Soviet domination (Brzezinski, 1956; Pipes, 1954). Contributing to the Cold War confrontation was not the only preoccupation of historians of Eastern Europe, but nonetheless the field has been faced with a need to reinvent its basic framework after the dissolution of the Soviet Union in 1991.

Many scholars, including the author of the previous article in this encyclopedia (Blackwood, 2001), predicted that such a redefinition would be extremely difficult and the field would eventually dissolve and/or integrate with the broader European narrative. This process is far from complete and while the field has been shifting in that direction, it still retains its specificity and can be approached as a separate unit. This article focuses on two related themes. First, it examines what criteria are used by historians to define what counts and what does not count as 'Eastern European history.' Second, it surveys new work in the field, outlines how it is related to older historiography and how it communicates with new trends in historical scholarship. In conclusion, it offers several reflections on what kind of light some recent geopolitical shifts such as the EU enlargement (in the 2000s) and the Ukrainian crisis (2013–14) shed on Eastern Europe as a concept and what they portend about its future.

The chief difficulty facing historians who insist on the validity of Eastern Europe as a historical term is the lack of Eastern European identity among the peoples of the region. This obstacle is much less pronounced for nation-state (German, Polish, Hungarian, etc.) or imperial (British, Soviet, Habsburg, etc.) historians where the domain of study is much more clearly defined through subjective identities and/or political boundaries. Eastern Europeans rarely think of themselves as Eastern Europeans per se; all studies show that this identity is either nonexistent or insignificant in comparison with national, religious, or pan-European identities. In this sense, the field of Eastern European historical studies can be seen as 'inorganic' – its origins are rooted in global conditions largely beyond Eastern Europe's control (imperial rivalries, World Wars, the Cold War, etc.). In other words, the field owes its existence largely thanks to an outsider 'gaze' cast upon the region.

One of the most authoritative surveys of the region's twentieth-century history (Rothschild and Wingfield, 2008) is entitled *Return to Diversity*. The title unequivocally implies that the region has returned to its historical 'norm' (diversity) after half a century of 'forced' convergence in the Soviet Block. Eastern European 'return to diversity' is tied with one of the original lenses through which the region has been perceived – the allegory of a bridge between East and West, a place where cultures meet and give birth to numerous mixed formations. The validity of the 'return to diversity' thesis is implicitly confirmed by recent developments in political science and in the new subfield of 'transitology' in particular; one of transitology's chief aims is to explain the diverging trajectories of states that seemed so similar politically prior to 1989. Many scholars search for deeper historical causes such as early modern democratic experiences to account for this phenomenon. What are the main features amid this newly reconstituted diversity that form the common denominators large enough to validate speaking of a common regional history?

Perhaps the oldest division line separating 'Western' and 'Eastern' Europe is of a religious nature. Starting with the split of the Roman Empire into two halves, through Byzantine-Greek Christianization of much of the Balkans or the Kievan Rus, the Great Schism of 1054 or the Muscovite 'Third Rome' ambitions, the rift between Latin and Greek Europe has always been noticeable and usually deep. In 1983, the Hungarian historian Jenő Szűcs suggested that parts of what was then known as 'Eastern Europe' (Poland, Czechoslovakia, Hungary) were miscategorized. These areas have always been, he argued, a part of the 'Western civilizational sphere' since their adoption of Christianity from Rome and not from Constantinople. The Orthodox faith and administration, the Cyrillic alphabet or the

absence/weakness of Protestant Reformation are thus posited as the original and decisive factors explaining the differences between the two parts of the continent. In Poland and Hungary, the image of these two countries being the 'bulwarks of Christian faith' containing the Orthodox and (more typically) Islamic element has become a part of national consciousness in the early modern period. In general, this basic distinction is rarely questioned, but there is little new scholarship that would operate within religiously defined frameworks, especially after the 'atheistic' communism cast aside what had been earlier perceived as a defining feature of Russianness – Orthodox religiosity.

Another frequently drawn and almost as old a distinction is of economic character. The 'Iron Curtain' ultimately did not fall between the ports of Stettin and Trieste as Winston Churchill announced in 1946, but closer to the ports of Lübeck in Germany and Burgas in Bulgaria. This seemingly incidental detail of geography must have intrigued many historians. The border between West and East Germany eventually materialized very close to the Elbe River – one of the major fault lines drawn by economic historians. It separates the world of nascent commercialization of agriculture in Western and the second wave of feudalism in Eastern early modern Europe. Naturally, the final course of the border between East and West Germany had nothing to do with economic history and a lot to do with where the Allied and Red Armies met in 1945. Still, the next four decades made the Elbe River divide, already bleak in 1945, plainly visible again. Eastern Europe, besides being popularly and somewhat stereotypically viewed as Western Europe's poor relative, is understood by some economic historians to be a region where the second wave of feudalization and deurbanization took place just when Western Europe began to urbanize and ready itself for the industrial revolution. Both the forced Soviet-style industrialization and the current EUintegration are sometimes framed as attempts to close this old gap. The initial advancements achieved by the Soviet Block economies between 1945 and mid-1970s have been interpreted by a prominent historian of the region, Ivan Berend, as the region's temporary 'detour from periphery,' a detour brief in its promise since the region returned to its point of departure after the stagnation and collapse of the 1980s (Berend, 1996).

Jenő Szűcs has also pointed to the spread of civil and municipal liberties in the late Middle Ages, exemplified, for instance, by urban settlement based on the German (Magdeburg) law as a factor with momentous political consequences for where the border between 'Western' and 'Eastern' Europe eventually crystallized in political terms. The substantial experiences with (qualified) democracy, civil rights, and the rule of law in, e.g., the early modern Habsburg Empire or the Polish–Lithuanian Commonwealth, were occasionally cited by Cold War era historians as features distinguishing 'democratic' and 'Central European' parts of the Soviet Block from the 'despotic' territories traditionally administered from Moscow and Istanbul. In this context, the stable Czechoslovak democracy of the interwar period was frequently seen as evidence that this state was firmly in the 'Western' sphere while all the other 'children of Versailles,' who eventually drifted toward various forms of authoritarianism, were truly in 'Eastern Europe' (Seton-Watson, 1945). This way of viewing Europe became more popular especially after the suppressed 'prodemocratic' unrest in Hungary, Czechoslovakia and Poland (1956, 1968, 1970, 1980) and after the 'successful' democratization in those countries and 'problematic' democratization in Belarus, Ukraine, or Russia after 1989/91.

Religious, economic, or political are merely three among numerous other 'macro' lines according to which the map of Europe can be divided. As Larry Wolff reminds us, before Peter the Great's introduction of Russia onto the European diplomatic scene, the division of Europe into 'north and south of the Alps' had been much more firmly embedded in the European mind (Wolff, 1994). All lines of this type are of course arbitrary and depend on the kinds of questions asked and the historical period studied; no serious historian argues that one can define what Eastern Europe is and what its borders are precisely and conclusively. Nevertheless, the region's entanglement with communism in the twentieth century is a part of its heritage of that cannot be overestimated. Judging by volume alone, the twentieth century communist experience, with all of its extensive and complex tropes, is currently the main subject of study for historians of the region. This experience is strongly intertwined with more pan-European topics such as totalitarianism, World Wars, and superpower confrontation. If one adds the Holocaust, ethnic cleansing, forced population transfers, and all other 'terrible things that happened in the twentieth century,' what emerges is singlehandedly the most extensive subject of the region's historical research and the cornerstone of its historical memory.

Before surveying some of the major trends in historiography, it is worth mentioning that Eastern Europe borders with several well-established regions of historical scholarship: Russian/Soviet, Ottoman/Middle Eastern, German, Italian, Scandinavian, etc. The borders between them will never be rigid and the very impossibility of drawing even tentative lines in some areas lead to a new subfield of scholarship which focuses precisely on these mixed, ambiguous, and contradictory areas often called 'borderlands.' This field is of course not limited to Eastern Europe, but some of its provinces such as Galicia (Frank, 2005), Transylvania (Case, 2009) and towns such as Lvov (Amar, 2011) or Salonica (Mazower, 2005), due to their ethnic, religious, or cultural diversity, have by now become recognized as exemplary cases demonstrating just how immensely complex and difficult to disentangle borderland territories can be. It has to be kept in mind, however, that what might be described as a 'typical' Eastern European borderland by an outsider might be considered to be an integral element of a core ethnic area by a local nationalist (Transylvania for some Hungarians or Romanians, Galicia for Poles and Ukrainians).

While historians rarely argue about whether a given region or topic belongs to, for example, Eastern European or Russian studies, what did emerge as an important contender for Eastern European studies is the idea of Central Europe and the scholarly movement it inspired. This term has its roots in the imperial German concept of *Mitteleuropa*, but it reemerged in a different context half a century later. It was reinvented and refashioned by anticommunist dissidents such as Milan Kundera, Czesław Miłosz, and Danilo Kiš. Kundera's essay "The Tragedy of Central Europe" (1984) is often perceived as the moment when the idea was reborn. In essence, the argument was that Central Europe (by which Czechoslovakia, Poland, and Hungary were usually meant) has always belonged to

Western Europe in civilizational terms, but has been 'kidnapped' and politically imprisoned in the Eastern European sphere by the Soviet power. While the political implications of this intellectual movement became largely irrelevant after 1989 and certainly after the EU extension in 2004 and 2007, a new wave of scholarship inspired by them emerged and found institutionalization in, e.g., the Central European History Journal.

This new 'Central European wave' is located in an intermediate position between the old German and the dissident ideas; the late Austro-Hungarian Empire, with its cosmopolitan and culturally vibrant cities of Vienna, Prague, Budapest, or Cracow, are painted as 'archetypically' Central European sites. Scholars who identify themselves as Central Europeanists come from various backgrounds; not infrequently they are historians of German-speaking lands who reach out to areas that had a rich record of contact with German culture and administration. While this field does not compete with Eastern Europe in any direct sense, its position has been steadily ascending vis-à-vis its neighbor for several reasons. The late Habsburg Empire has enjoyed a remarkable reputational renaissance, largely because its many imperfections do not stand a comparison with all the tragic events that befell the region after the Empire disintegrated. The Empire has been portrayed as a kind of a proto-EU project where many ethnicities and languages coexisted in relatively peace within one political unit for centuries (Oscar Jászi, 1929). Furthermore, fin-de-siècle Vienna or Prague with world-class artists and intellectuals such as Freud, Mahler, Wittgenstein, or Kafka are commonly seen as manifestations of European cultural vibrancy at its best (Schorske, 1979). But most importantly, the inhabitants of Prague or Cracow virtually universally prefer being spoken of as Central Europeans rather than Eastern Europeans. The success of the Central European University in Budapest shows that there is plenty of willingness to cooperate and produce knowledge under a common Central European banner.

Central European scholars such as Pieter Judson or Rogers Brubaker have been at the forefront of the study of nationalities and nationalism – a traditional Eastern European topic – and the late Austro-Hungarian Empire has been one of the main case studies used to address issues such as national identity formation, national cohesion and indifference, bilingualism, or mixed families (Judson, 2006; Brubaker, 1996). Following Eugene Weber's groundbreaking book *Peasants into Frenchmen* (1976), historians of the Austro-Hungarian Empire demonstrated how a nineteenth-century region inhabited largely by villagers and small town folk with local (geographical, tribal, familial) or religious identities turned into region as we know it today – inhabited by Germans, Czechs, Slovaks, or Croats (King, 2002). One of the leading questions still to be answered is 'when (and why) nationalism began to hate' – i.e., how an initially 'progressive' ideology of intellectuals intent on helping the 'small peoples' suffering under oppressive imperial government transformed itself into one of the main sources of conflict in twentieth-century Europe (Porter, 2000). In this context, the transatlantic gaze of 'outsiders' and the multiethnic composition of the Austro-Hungarian Empire helped to avoid the trap into which many native nation-state historians fell – writing biased national histories favoring one particular ethnicity and contributing to keeping the flame of nationalism alive. This type of approach to the study of nationalism has seen fruitful application to the Soviet area as well. Terry Martin's *Affirmative Action Empire* (2001) demonstrates how illusory was the Soviet (and global) conviction that the so-called 'nationalities question' had been solved in the borderlands of the Soviet Union and why this issue came back with a vengeance in the late 1980s as the Union disintegrated along its ethnically defined internal borders.

How the relationship between 'Eastern' and 'Central' European fields is going to evolve is impossible to predict; both are products of a unique set of circumstances and both are likely to find their place within a larger European or global framework. Immediately after 1989, the traditional Eastern European (and to some extent Soviet) field was supplied with new materials accessible at the local archives. The first wave of research focused on the early period (1945–56) around the theme of communist takeover and Stalinization (Kenney, 1997; Connelly, 2000). The current consensus on the subject has been well summarized by Joseph Rothschild and Nancy Wingfield:

> Today we recognize that many of the Western academic analyses of the 1950s and 1960s subscribed to exaggerated images of a rigid blueprint that supposedly guided Moscow and the local East Central European Communists in implementing the procedures and arrangement that Stalin eventually selected to give effect to his perception of Soviet hegemonial requirements. But while correcting this early presumptions, we should not throw out the baby with the bath water. For though there probably never was a rigid uniform Stalinist plan to be imposed in cookie-cutter fashion on every state and society of East Central Europe without regard to diverse national histories, institutions and complexities, the general overall similarities in Soviet and local Communist behavior throughout the area in the first decade after World War II strongly suggests a unified conceptual framework – more flexible at the beginning than toward the close of that decade, never entirely absent yet also never absolutely rigid.
>
> Rothschild and Wingfield, 2008: 75–76

A lot had been known about Stalinist terror and crimes, but new evidence allowed scholars to present detailed findings and provide more accurate statistics (Naimark, 1995). Documenting and making sure the memory of various types of transgressions committed by the Soviet and puppet regimes does not disappear became the main preoccupation of many locally based historians (Applebaum, 2012; Kusnierz, 2013); special national institutes (e.g., the Institute of National Remembrance in Poland) were established precisely with that goal in mind. The same observations apply to issues such as Nazi occupation and the Holocaust, most of which had been if not explicitly suppressed, then not very thoroughly explored by historians under communism, especially the period between September 1939 and June 1941, when Hitler and Stalin were allies (Gross, 1988). Continuing the tradition inaugurated by Czesław Miłosz (1953), intellectual historians maintained their interest in the strength of communism's 'Hegelian bite' – trying to understand why Marxism appealed to so many Eastern European (and not only) intellectuals and what was their relation with the regime and its ideology (Shore, 2006).

One aspect of the Stalinist period in Eastern Europe (1945–53) in particular that could not have been explored earlier was the issue of forced population transfers and deportations.

While historians in the West could argue to what extent these transfers were voluntary or not, historians in Eastern Europe had to accept the official party line that spoke of their voluntary nature. Czechoslovakia, Poland, and East Germany were in an ambivalent position due to the way the Germans were deported (1945–48) on the one hand and due to the 'alliance' of 'brotherly nations' that was now imposed on them by their Soviet supervisors on the other. Hence the spike in research on this topic after 1989 (Ther and Siljak, 2001). Overall, the findings show that the scale and brutality of post-1945 deportations have been much greater than it had been suspected. The ironically disturbing conclusion is that it was eventually Joseph Stalin who helped to bring the old nationalist fantasy of ethnically pure states to fruition while where no clear ethnic separation took place (e.g., Eastern Ukraine, Southern Slovakia) – tensions are still high today, not unlike in the interwar period.

The semblance of uniformity within the Soviet Block did not fool too many observers. Already in the 1950s, the term 'national communism' was coined to capture the developments in Yugoslavia and then it was aptly transferred to describe post-1956 Poland, Hungary, and *Ceaușescu's* Romania in particular (Verdery, 1991). Not unlike the 'varieties of capitalism' literature in the West, experts on Eastern Europe were quick to discern the characteristics of each 'national communist' system. Hungary became known for its relatively open and prosperous economy, Poland for its mild censorship, East Germany for the secret police, Romania for its familial nepotism. After 1989, historians could start examining how much of 'block' there really was in the Soviet Block beyond prima facie political, military, or economic ties and similarities; the more research is carried out, the less the appearances seem to correspond to the underlying reality.

With the Cold War still in full swing in the 1980s, it was difficult for the scholars of the region to avoid a bipolar division of the field into anti- and procommunist camps; often one could not escape being labeled either a 'cold warrior' or a revisionist with cryptocommunist sympathies. This characterization is no longer valid. The revolutions of 1989 were immediately followed by a wave of scholarship that sought to understand why the system collapsed so quickly. The 'history of the present' written by Timothy Garton Ash immediately after the events of 1989 (Garton Ash, 1990) has addressed many puzzles and new equally insightful research soon followed (Maier, 1997). But after the initial astonishment subsided, scholars reversed the question and asked: what made the system survive for so long despite its seeming incompatibility with the region's societies? Thus the earlier scholarship on the establishment of communist power (1945–48) was recently complemented by studies of the Brezhnev era of *zastoy* (stagnation) and looked for deeper sources of the regime's stability. Many young historians study the patterns of consumption (both material and cultural) in communist societies and arrive at intriguing findings highlighting just how little was understood about how the system worked internally on an everyday basis (Mazurek, 2010). Various polls conducted after 1989 consistently show that there exists a large amount of nostalgia for the bygone days, which suggests that the regimes must have enjoyed some real support. Studies of the 'gray economy' demonstrate that reliance on official figures on the planned economy can be misleading as they capture merely one aspect of a more dynamic and complex economic reality.

Already in the eighteenth century, the image of Eastern Europe was often associated with backwardness. Poor sanitary conditions, underdeveloped infrastructure, general poverty, and disorder were impressions often conveyed by eighteenth century 'Enlightened' travelers. In German vocabulary, the term *Polnische Wirtschaft* became synonymous with a badly managed economy. But it was also, among others, Eastern European émigré scholars who were instrumental in developing a comparative method of developmental studies, sometimes given an overall heading of 'modernization theory.' The acute awareness of their country's industrial weakness was one of the factors that propelled the Soviet leadership, and Stalin in particular, to launch a program of rapid state-sponsored industrialization in the 1930s. This method of economic development has then been transplanted onto Eastern Europe, especially between 1948 and 1956. There has been an ongoing debate among historians as to what extent the communist experience can be understood as a modernization process. There is no consensus, but certainly an agreement that any evaluation depends on the country – underdeveloped countries such as Bulgaria or Romania benefiting more, more developed, as Czechoslovakia, less – and the field of human endeavor (culture, gender relations, economic, politics, etc.) in question. Many historians do agree that the dramatic socioeconomic transformation of the 1950s and 1960s could be characterized as a breakthrough in areas such as public education, social security and welfare, gender equality, urbanization, industrialization, etc. The debate continues whether the human cost of these transformations was acceptable while some historians reject the modernization framework altogether. Especially those influenced by postmodern critiques of the modernization paradigm, such as Maria Todorova (1997) or Kate Brown (2004), argue that it is in the often self-serving eye of the beholder that ideas of superior or inferior development originate and should be rejected as both uninformative at best and prejudiced at worst. Scathing critique of the Western 'colonizing' gaze on Eastern Europe has been voiced especially by Todorova, who also expressed well-taken criticism of the idea of Central Europe as a project meant to include some in the elite 'European' club at the exclusion of the others – in particular the Balkans.

World War II is an important chapter in any region's history, but it left a particularly heavy mark in Eastern Europe. In his recent book entitled *Bloodlands*, Timothy Snyder (2010) documents just how much the region squeezed between Russia and Germany suffered, not only during World War II, but also in the 1930s (*Holodomor* in the Ukraine, Stalinist Purges) and after the War. The region is located precisely at the fault line between the two most murderous regimes in history and this basic fact has to be comprehended by anyone who studies it. The role of Eastern Europe as a victim of forces beyond its control has been a recurrent motif in the region's literature and historiography. According to Milan Kundera, the experiences of World Wars and imperial domination molded a unique national subjectivity in the region, a subjectivity constantly aware of its very existence being fragile, in danger, and at the mercy of larger powers. Poland has been portrayed already by early nineteenth century romantic writers as

a 'Christ of the Nations' redeeming the sins of other nations. This tradition has remained very much alive in Polish historiography. While Snyder and other scholars never push their metaphors so far, there exists a tradition of writing about the Polish–Lithuanian Commonwealth and its peoples from a victimized perspective – one of the definitive works on Polish history, written by the British historian Norman Davis, is entitled *God's Playground* (1979).

The history of Ukraine in the twentieth century is often written from a similar perspective – as primarily a victim of two regimes, Soviet and Nazi. Karel Berkhoff in *Harvest of Despair* (2004) provides an in-depth narrative of how the experience of Nazi occupation looked for the 'ordinary' Ukrainian, what were its daily dangers and deprivations. Mark Mazower's (2008) comprehensive survey, *Hitler's Empire*, is the first comparative account of the Nazi occupation in the entirety of Europe. Mazower demonstrates that the term 'occupation' did not entail an even remotely similar set of experiences for 'Western' and 'Eastern' Europeans, with the General Government and the territories of today's Ukraine and Belarus being the most brutalized and exploited of all. This victimization narrative has been recently challenged and problematized, however. Works of Jan Gross (2001), starting with *Neighbors: The Destruction of the Jewish Community in Jedwabne* – a depiction of how local Polish population organized the killing of several hundred of their Jewish neighbors in the summer of 1941 – have made it impossible to hold that local populations were merely passive bystanders. The categories of resistance and collaboration have been recently revised and nuanced by numerous authors and the topics of postwar popular justice, retribution, and memory have seen collaborative efforts by the most renowned authors in the field (Deák et al., 2000).

The intersection of Eastern European and Jewish histories has been a vibrant field of study in the last two decades. While the Holocaust and Jewish studies in general were largely a taboo subject in the first several decades following the war on both sides of the Iron Curtain, these topics have seen a great deal of attention (including some major controversies) recently. Ranging from micro-studies such as Helmut Walser Smith's (2002) work on the small German town of Konitz (now: Chojnice) before the Great War to broad surveys spanning several centuries (Slezkine, 2004), Jewish history and European history are finally put into dialogue with each other. Poland has seen a wave of historically informed cinematography on the issues of Polish role in Jewish extermination – a promising sign showing that is no longer a forbidden subject it had been for half a century. The process of coming to terms with historical memory and issues of guilt and responsibility has been addressed by Charles Maier in his evocative essays (Maier, 1988) and many historians followed suit.

Historians of Eastern Europe, although often preoccupied with some of the 'traditional' topics outlined in this article, have not remained unaffected by recent trends in historical scholarships. The field has seen innovative work in gender (Wingfield, 2006), urban (Thum, 2011), and everyday history (Healy, 2004). Historians have also paid attention to 'subaltern' groups often overlooked in 'traditional' political or international histories: children (Zahra, 2011) and underprivileged ethnic groups such as the Roma. The crimes committed against this particular minority have recently emerged as one of the main topics of scholarship, finally filling a gap in the literature (Lewy, 2000). Environmental history has been on the rise as well (Dawson, 1996). Traditional areas such as imperial history have in consequence received less attention, but there have been some groundbreaking work in this area as well (Plokhy, 2014). It is impossible to do justice to even a small fraction of new scholarship in this short article, but it is beyond doubt that Eastern Europe as a field remains at the cutting edge of historical scholarship and in stimulating dialogue with the rest of the discipline.

The calls to integrate Eastern European history not only with continental, but also global, history, have not remained unanswered. Naturally, the global approach has been most useful for historians of empires. Both the Austro-Hungarian and the Russian Empires have witnessed a sustained effort to reconnect their history with global agenda such as slave trade, global commerce, colonial expansion, or racial relations, issues which had been often marginalized earlier due to the urgency of military, diplomatic, and national questions. Especially the younger generation is keen on showing how the region they study participated in and influenced global movements such as the Renaissance, Enlightenment, birth of mass politics, origin and spread of technological advances, etc. This focus on interconnectedness, exchange, and mutual influence emerges as a dominant motive of the current doctoral works on the region.

Tony Judt's *Postwar* (2005) has arguably been one of the first attempts to put Western and Eastern European history back together into one integral whole. It took one of the greatest minds of the generation to achieve this monumental and (not very long ago) hardly thinkable task. In 1989, the Berlin Wall was a symbolic and all-too-tangible expression of vast rifts splitting the heart of the continent. The last quarter century has witnessed all kinds of integration and interchange of unparalleled scale and intensity. The rapidity of these processes has exceeded all expectations and poses a challenge for historians and for the ongoing European integration project. Writing history is now a truly global enterprise and old nation-state boundaries of historiographies, though still strong, are being diluted every year. The recent crisis in Ukraine (2013–14) did show that some of the Cold War categories still remain valid and that the rift between 'Western' and 'Eastern' Europe is not yet fully leveled. At the same time, it is certain that the model of Eastern European studies as it was conceived in the Cold War era is a thing of the past. This model would not function well in the current political or cultural reality. Many actively resist the Eastern European label and the conditions for Eastern European 'commonalities' no longer exist – to mention just two major reasons. Traditional clichés do not work either. The old language of nationalism and xenophobia seems to win more votes in some 'old' democracies such as France than in the 'perennially nationalistic' Eastern Europe. The differences in political orientation of two countries often put into one category by historians – Poland and Hungary – were rarely greater than in 2014. On the other hand, the twentieth century and the last 25 years are just a fraction of the region's millennial history and historians tend to be able to resist 'pressures of the present' rather well. There is certainly enough of shared history in 'Eastern Europe' to keep the field alive and to what extent it will be perturbed by recent 'divergent' developments remains to be seen.

Abstract

Though meant also as a geographical classification for denoting the region between the River Elbe and the Ural mountains, the concept of 'Eastern Europe' is mainly used to expresses certain historically informed sociocultural differences within the continent. It carries heavy layers of ambivalence: Although the societies embraced by it all are regarded as 'European,' they do not come up 'fully' to the standard of what 'Europeanness' implies. In this ambivalent classification, the implicit norm is the West, and Eastern Europe remains as much Eastern, as it maintains its 'other than Western' character. Thus, the concept has always been deeply imbued with politics. On the part of Eastern Europeans, its inherent political character has manifested itself in continuous attempts to close up the East–West divide through adaptation to the Western norms of the time; on the part of the West, the same politicized attitude expressed itself in the interest-driven recognition/refusal of these Eastern attempts, having immediate consequences on the (re)drawing of the invisible political, economic, and military map of the continent of Europe. Such ambivalences also characterize deeply the current efforts to unite Europe. Moreover, they leave their mark on the internal social development of the region's societies, as well as having serious consequences in the continuation of their post-1989 crisis.

Introduction

'Eastern Europe' is as much a historically shaped sociocultural concept with contents and connotations that have changed markedly over time, as a reality of recurrently shifting geopolitical divisions. The standing aspiration of the region's nations has been their full integration into a unified Europe driven by Western values and norms. Although meant also as a geographical classification for denoting the region between the River Elbe and the Ural Mountains, the concept of 'Eastern Europe' is mainly used to express certain historically informed sociocultural differences within the continent. It carries heavy layers of ambivalence. Although the societies embraced by it all are regarded as 'European,' they do not come up 'fully' to the standard of what 'Europeanness' implies. In this ambivalent classification, the implicit norm is the West, and Eastern Europe remains as much Eastern, as it maintains its 'other than Western' character.

Eastern Europe: A Region with Clear Contours, but Opaque Borders

Customarily, Eastern Europe as a geographical concept is understood to denote the region positioned east from the River Elbe and west from the Ural Mountains. Such a geographical definition meets, however, insurmountable difficulties when translated into societies, nations, and states. As to the western border of the region, the River Elbe runs through Germany. Does this mean that German society is sharply divided into a 'Western European' and an 'Eastern European' segment? Similarly, the eastern border of the region – the Urals – cuts through Russia; does this mean that one half of Russia belongs to 'Eastern Europe,' while the other is part of the 'non-European East?' Further, if such fault lines divide one or more countries of the region, what are the implications of their presence: do they simply carry sociocultural differences of historical and ethnographical interest, or, does their persistence endanger the stability of the affected states, and, beyond, that of the continent itself? In short, if not simply a tool of geographical orientation, what then is the function of making the East–West differentiation within Europe?

Certain sociocultural differences on regional grounds can be observed in all societies. Still, despite the remarkable differences between Northern Italy and Sicily, nobody in our times would question Italian unity, and the belonging of the entire country to the core of the West. Likewise, even the linguistic division of countries like Belgium or Switzerland would not inspire anybody to doubt the integrity and genuinely Western character of these societies. Thus, the ambiguities in identifying the borders between Western and Eastern Europe arise from deeper layers of differentiation. Their essence is neither a neutral geographical classification according to the magnetic poles, nor a definitive and value-loaded gesture of clearly circumscribing 'togetherness' as opposed to 'otherness.' The concept of 'Eastern Europe' represents a mixture of the latter two, and carries the inherent ambivalence of such a combination. With the very same momentum, it signals undivided 'Europeanness,' and also some reservations toward it. Although the societies embraced by the concept are all 'European,' they do not come up 'fully' to the standard of what 'Europeanness' implies. In this ambivalent classification, the implicit norm is the West, and Eastern Europe remains as much Eastern, as it maintains its 'other than Western' character. Thus, the concept has always been deeply imbued with politics. On the part of Eastern Europeans, its inherent political character has manifested itself in continuous attempts to close the East–West divide through adaptation to the Western norms of a given time; on the part of the West, the same politicized attitude expressed itself in the interest-driven recognition/refusal of the

Eastern attempts, having immediate consequences on the (re)drawing of the invisible political, economic, and the military map of the continent of Europe.

The doubtfulness of the borders – both in the harsh physical and in the more subtle sociopsychological sense of the term – has inspired recurrent attempts to refine geographically founded geopolitical classifications by denoting important and 'meaningful' subunits within the region (Todorova, 1997). Probably, the most important of such attempts has been the repeated separation of 'Central Europe' from the rest of 'Eastern Europe.' The concept of Central Europe as a more 'Westernized' entity with coherent sociopolitical and cultural meanings on its own appeared mainly in nineteenth/twentieth-century public debates by writers, political thinkers, and philosophers (Kundera, 1984), but attempts at the political realization of togetherness and simultaneous separation from the rest of the region's nations also came to the surface among the goals of the sweeping political movements of 1848, 1918, and the late 1980s.

However, the ideas of 'Westernizing' Eastern Europe certainly are not the fresh production of modern times. Various grandiose experiments for their realization date back as far as the time after the fall of the Roman Empire. Since those distant days, the history of the region has been accompanied by heated debates over the 'belonging issue,' which, in turn, has gradually become a decisive aspect of the self-perception and identity struggle of the people living on its territory. The East–West divide, despite its opaque character, has proved extremely strong during the past 1000 years of European history, serving a variety of social, political, military, and economic interests both within and between the countries of the European continent. With this historically elaborated comprehensive political meaning of the concept, 'Eastern Europe' has been as much a point of departure for Western self-identification as for the shaping of programs to combat those 'historic illnesses' that have hindered certain societies from becoming parts of Europe proper. In other words, up to the time of writing, 'Eastern Europe' has been considered the embodiment of the major historical failures of the European continent. It has symbolized the stone-hard limitations of creating a Europe without any subdivisions, and has also represented the accompanying feelings of discomfort and frustration. In the course of the century-long failed efforts, these feelings have grown to become self-perpetuating mutual prejudices, which have exhibited an ever-stronger influence on shaping politics of the East–West cohabitation. The persistence of these prejudices cannot be ignored when attempting to understand the difficulties that the current program of European integration (see point 3 below) has to face in the course of its day-to-day realization.

The Historical Roots of Eastern Europe's One-Sided Development

Historians, political thinkers, writers, and philosophers seem to be in full agreement on identifying the emergence of 'the three historical regions of Europe' (Szücs, 1988) in the aftermath of the Barbarian conquest against the late Roman Empire, which resulted in the division of the occupied territories between Europa Occidens, Byzantium, and a distinct transitional territory in between. This latter region – the historical forerunner of Eastern Europe – occupied a halfway position in all senses of the term. It was neither 'Western,' nor 'Eastern,' but an ever-changing mixture of the two. First, the region's geographic placement exposed it to frequent attacks from both of the neighboring big powers, each of whom regarded themselves as the genuine heirs of the late Roman Empire – the Frankish Empire and Constantinople. Second, the shaping of the region's decisive religions, traditions, and ethos was put also under dual pressure from the West and the East alike. As pointed out by the influential work of medievalists and historians of political ideas (Gerschenkron, 1962; Said, 1978; Szücs, 1988; Wolff, 1994), although the people of Eastern Europe took up Christianity early enough in their history, the subsequent lasting Mongol, Ottoman, and Russian invasions revitalized a number of 'Eastern' features in their social relations, institutions, faith, and the running of their daily life. Third, as it has been demonstrated amply by recent studies in comparative history and historical anthropology (Gerschenkron, 1962; Said, 1978; Konrád and Szelényi, 1979), the states of the region as potential actors of modernization played an ambivalent role in the Premodern era: although the late Medieval centuries brought about absolutist reigns similar to those in the West of the time, the actual function of the Eastern European absolutist rule was to reinforce the estate-based power of the landed nobility – while their Western counterparts prepared the soil for the take-off of capitalism, democracy, and modern bourgeois development. The repeated events of military occupations, wars, mass uprisings, and the subsequent hurried efforts at reconstruction recurrently blockaded the crystallization of fundamental institutions of statehood and administration. Instead, these events usually concluded in hasty and forceful attempts of the conqueror to employ central power to eliminate the 'historic losses,' at all social and political cost. Such attempts at forced and inorganic modernization, however, caused lasting deformations in the sociopolitical order that have had a far-reaching impact on the development of the affected societies.

In assessing the potential and limitations of corrective societal actions, the most dramatic consequences shaping both politics and societies in modern times were discussed extensively by sociologists and political scientists in the 1980s and 1990s (Kochanowicz, 1997; Garton Ash, 1993; Arato, 2000). According to the virtually unanimous conclusions of these studies, the historically informed and persistent deformations of Eastern European societies can be summarized in three main features that clearly distinguish them from their contemporaneous Western counterparts: (1) the one-sided development of nationhood and national identity (which led easily to repeated waves of radical populism and irredentist nationalism); (2) the underdeveloped nature of civil society (which recurrently has provided natural justification for the states' inclination to gain oppressive power over people's needs); and (3) the periodic disappearance or, at best, weak institutionalization of democratic governance, which has been the cause of loose public control over administration and economic management, and which also can be seen as being responsible for the lasting symptoms of social disintegration in the region. Indeed, the hopes that the collapse of communism and the expansion of

the European Union eastward would finally entrench liberal democracy has been tested by contentious politics (some of it centered on ethnic relations) and the rise of political elites intent on consolidating their own power through appeals to a confrontational nationalist rhetoric and fundamental correctness of elite leadership – with Viktor Orbán of Hungary being a case in point.

These historic deformations became sources of dangerous political conflicts around the beginning of the twentieth century. After the failed revolutions of 1848, which, for a century to come, represented the last heroic attempts of the nations of the region to (re)gain national independence and create their state which would guard civil rights, law and order, and free capitalist development, the societies of Eastern Europe faced exclusion from Europe proper, and reacted accordingly – in a frustrated and hostile manner. As historical research has demonstrated convincingly (Konrád and Szelényi, 1979; Schöpflin and Wood, 1989), the outbreak of World War I cannot be explained without considering the preceding unhealthy nationalist rivalry within the borders of the increasingly ineffective, but still oppressive Austro-Hungarian monarchy, and the deep tensions between the cultural–political formations of the communities and their governing states in all the surrounding societies. Again, the outbreak of World War II cannot be explained merely in terms of the clashing political and economic interests of the leading powers of the European continent; the picture remains disturbingly incomplete without taking into account the extremist aspirations of Hitler's Germany and its allies to find a 'final solution' for the century-long diseases of confused cultural and national identity, and also without considering their deeply embedded attempts to claim new territories and borders for their historically 'stolen' nation states (Bibó, 1991). However, not only the two World Wars, but also the 'invention' of the two, diametrically contrasting ways of totalitarian ruling originate from the same roots. As argued in Arendt's and Bauman's studies that have become classics of postwar social science, one can find in their creation the same forms of traumatized, oblique, frustrated, and confused nationalism, and the unstable institutions built on them (Arendt, 1958; Bauman, 1989). While the Nazi way of totalitarian rein put the superiority of race and nationhood at the center of its legitimizing ideology, communist totalitarianism – with its aim of radically transcending the past – denied the role of nationhood as such, and attempted to substitute it with values of internationalism and enforced equality. However, despite the viciously different responses of the two forms of totalitarianism, the emotionally heated attitudes toward nationhood and national identity, the conflictive relationship between the state and people's spontaneously formed communities, the weak observance of rights and law, and, consequently, the enduring harm done to individual freedom remained key problems of Eastern European societies until the end of the twentieth century. True, the modernization of the economies and societies of the region, and the ultimate closing down of the East–West divide belonged to the core of the communist program of the four decades following World War II. However, the domino-like collapse of the Soviet-type regimes in 1989–90 testified sharply to the failures of these attempts, and drove back the societies in question toward the lost track of classical capitalism. Perhaps, the principal evidence of the failures is the fact that with the sweeping events of the late 1980s, the allegedly abolished problems of the interwar years have come to the surface with dramatic intensity: Widespread poverty, intense racism, extreme social marginalization, sharp inequalities of income and wealth, pervasive corruption, and weak legal protection of defenseless communities and individuals are among the most disturbing troubles of Eastern European societies at the time of writing. In order to understand the unfolding of these problems, a brief examination has to be made of the legacy that the communist systems of Eastern Europe have left behind.

Eastern European Societies: From Where to Where?

As a number of recent studies in social and political history have shown, despite the steps taken throughout the 1970s and 1980s toward economic and political liberalization in different countries of the region, the fundamental features of the communist system of Eastern Europe remained unchanged until the late 1980s (Kornai, 1991; Garton Ash, 1993; Arato, 2000). Backed by the military, political, and economic monopoly of the all-embracing Soviet force in the region, the communist party states of the affected countries maintained their power over all the segments of the economy and society, including people's most private matters of career choice, marriage, childbearing, daily consumption, or cultural taste. Aside from the tools of enforcement solely in the hands of the ruling communist parties, the bases for such an extraordinarily extended power were provided by two major deeds: the concentration of 'people's property' in the hands of the party-ruled state, and the institutionalization of the day-to-day control over society through compulsory full employment. As comprehensive studies on the working of the socialist economy have demonstrated (Kornai, 1991; Sik, 1991) the concentration of all the means of production was intended to induce economic rationality through the centrally prescribed production commands driven by the Plan, while compulsory employment was seen as the base for fair shares from distribution and, simultaneously, as an effective means to combat poverty. However, such a structure turned against the initial goals rather quickly: from the early 1960s onwards, the Eastern European communist regimes, one after the other, had to face recurrent deep economic crises, and an increase in social tension originating from the 'dictatorship over needs' (Fehér et al., 1983) that led to nothing else, but the equality of poverty on an unparalleled scale. Thus, the mere maintenance of the regimes required certain concessions: the most important among them were the rehabilitation of the family as a legitimate sphere of people's undisturbed privacy, and the tacit acceptance of the slow evolution of a second, informal economy.

However, these concessions proved to be powerful tools in societies' hands slowly to erode, then effectively to decompose the oppressive structures above them. Eastern European sociological, social–historical, and economic research of the 1970s and 1980s provided a rich literature of these multifaceted processes which, in retrospect, can be regarded as the direct ascendants of the radical social upheavals after 1989–90 (Vajda, 1988; Staniszkis, 1991; Szalai, 1991; Kochanowicz,

1997). The move away from classical socialism was unstoppable. First, ever-spreading participation in the informal economy gradually took a lead in determining the standard and forms of consumption for substantial layers of society; thus, the tacit acceptance of people's informal work and their partial withdrawal from party control, even in the strictly regulated socialist workplaces, was also in the immediate interest of those in power – otherwise, the communist parties would have risked unmanageable crises in production and consumption that could have led to the swift fading of the justification of their 'blessing rule.'

Second, the family-based framework of the informal economy provided a forum for learning a number of market-related skills and thus assisting the underground continuation of the interrupted embourgeoisement process. Such an underground preservation of officially denied values, attitudes, skills, and socioeconomic arrangements later proved crucial in the post-1989 systemic changes of returning to a capitalist/bourgeois track. Third, the informal economies of Eastern Europe complemented the ever-impoverishing state-run welfare provisions with community-based social services, and with slowly elaborated forms of secondary redistribution. Thus, they had a role in correcting the inadequacies of the distribution of incomes driven from the 'first' economy, and also in developing those market-conforming forms of social protection, which then, effectively, assisted the transition process amid the rapid withering away of state distribution some decades later. In short, the informal economy and the social relations around it gradually became a second – mostly hidden – regulator in the functioning of the communist regimes, and an important second pillar in organizing the daily life, well-being, aspirations, and life careers of substantial groups of Eastern European societies.

The emergence of this second system had also serious deficiencies. As sociological research on the malfunctions of the 'socialist' welfare states has evidenced it (Deacon and Szalai, 1990; Kochanowicz, 1997; Atal, 1998; Lessenich, 2000), those who, for a range of varied reasons, could not participate, became increasingly dependent on the state that gradually intensified their defenselessness, instead of mitigating it. With the spreading and tacit acceptance of the regulatory role of the informal economy, the nonparticipating groups were designated as 'misusers' of the public resources, and cuts in assistance for them were approved on a mass scale. Thus, the spreading of participation in the informal economy gave rise to serious social divisions which, amid the troublesome economic conditions of the post-1989 years, eventually became an open war between the 'non-diligent' poor and the 'industrious' nonpoor.

A further shortcoming of the dual system was its weak institutionalization: any claims for the formal acknowledgment of informal work collectives, service providers, interest representations, and the like were seen as open attacks against the principles of the prevailing order, and were treated as political crimes. On these grounds, the informal economy became a battlefield for freedom, but at the same time, the political connotations of participation further hindered its institutionalization. The negative consequences of such a development came to light mainly after the collapse of the old rule. As in-depth studies of the democratic potentials of Eastern Europe have pointed out convincingly (Staniszkis, 1991; Berend, 1993; Arato, 2000), despite widespread earlier practices, civil society has proven to be extremely weak, and the new system could hardly count on its provisions, protective associations, and community-run services amid the deep 'transitional crisis' of the 1990s.

The weakness of civil society has given rise to serious crisis phenomena amid the two intertwined major processes of postcommunist transition: the decomposition of the formerly unlimited power of the central states, and the privatization of the earlier anonymous 'people's properties.' Paradoxically, the earlier resistance to the state as oppressor is now quite clearly being reversed, and while the various corporate bodies and interest alliances only clung to the state distribution policy out of fear and defenselessness, they now make angry claims on it. Behind the opposing principles of privatization intended to 'regulate' the plundering of public assets, one finds intensely competing demands for compensation. Having the arguments justifying these claims accepted and embodied in the legislation is a question of raw political force. As comparative economic studies in the region have demonstrated with ample empirical evidence (Róna-Tas, 1994; Stark, 1996), in this way, privatization and the creation of a bourgeoisie is the direct function of the latent bargaining positions established over past decades. Hence, the process of privatization has led to a jump in uncontrolled and unregulated inequalities of income and wealth, and to the emergence of a new, prosperous elite with little legitimization. At the same time, the process has produced masses of victims at the other end of the scale. Besides depriving them of any access to the newly distributed properties, the easiest compromise to find resources to meet the hunger of the vocal groups has been to cut back sharply on state expenditures on welfare and social services. With these steps, however, Eastern European transition societies have produced vast numbers of chronic poor, whose fate has been extreme social marginalization. Thus, despite the initial hopes of 1989–90, massive poverty and the accompanying syndromes of dramatic social disintegration have not disappeared with the recovery from the crises of the early 1990s, but have become the decisive indicators of a still non-Westernized path of current Eastern European development. The conflicts that arise from this situation have further consequences. The still excessive presence of the state in most of the region's economies, as well as the understandable open aspiration of the earlier overblown state bureaucracy to reinforce its own position of power, at most only help broad strata of societies to reach the recognition that the creation of a private market in the Western sense is a 'foreign' prescription for the process of embourgeoisement in the region – their 'genuine' path still leads through nationalized modernization. Thus, it is hardly surprising that Western and Eastern economists, sociologists, and political scientists analyzing the major sociopolitical processes of postcommunist transition arrived at largely consensual conclusions by the late 1990s (Kochanowicz, 1997; Standing, 1997; Arato, 2000). There seems to be a general agreement that the spreading of anti-West feelings provides a fertile soil for heated nationalism, aggressive racism, and the reemergence of authoritarian tendencies; hence, these recent tendencies in the changes of popular attitudes endanger seriously the once vivid hopes of creating a Europe without

boundaries. However, these unanimous warnings have little impact on actual politics: at best, social science reflects and informs the ongoing attempts of European integration, but can hardly influence it.

Eastern Europe's (Re)turn to Europe

Studies after 1989 suggested the persistence of a sharp East–West divide, much in accordance with sociocultural fault lines explored by earlier historical studies. It seems that in their post-1989 development, Eastern European societies have taken a lead toward increasing social disintegration between their adaptive majorities and the extremely marginalized minorities in long-term poverty. The states of new democracies are squeezed between contradictory challenges of marketization and combating social disintegration at the same time; due to the weakness of their civil societies, they have postponed repeatedly the addressing of the latter problem by creating the required strong welfare systems. As a result, the current social map of Eastern Europe resembles more some Latin American societies than those of the neighboring Western Europe.

Although meant also as a geographical classification for denoting the region between the River Elbe and the Ural Mountains, the concept of 'Eastern Europe' is used mainly to express certain historically informed sociocultural differences within the European continent. It carries heavy layers of ambivalence: although the societies embraced by it all are regarded as 'European,' they do not come up 'fully' to the standard of what 'Europeanness' implies. Such historically informed ambivalence characterizes deeply as well as the current efforts to unite Europe.

Yet contradictions and ambivalence in East European societies might shift in the near future. As of this writing, two forces or events might lead to fundamental changes in identities and interests of East European societies: the crisis of 2008 and Vladimir Putin's annexation of Crimea and destabilization of Ukraine. Regarding 2008, 'East European' countries have felt a sense of secondary status vis-à-vis their western neighbors – but not all of them. In deliberations over responses to the recession, and then to the crisis of the euro spurred by the threat of a Greek default on its debts, the voices of those publics east of Germany were not well heard. Instead, political and economic elites in Germany, Great Britain, and France (in particular, in Germany) for all practical purposes framed the discussions and decisions regarding austerity versus alternative policies, for example. How this Western hegemony in European Union decision making, and the results of such decisions, ultimately impact Eastern European economies, and from there public discourse and public opinion, remains to be seen. However, if such policies can facilitate resentment vis-à-vis the Western countries of the European Union, Russia's foreign policies might ultimately propel 'East Europe' further into the fold of 'Europe' generally. After Russian President Vladimir Putin has essentially annexed Crimea and then (according to much circumstantial evidence) supported separatists and a civil war in the eastern Donetsk region, Poland and the Baltic countries were especially vocal in asking that NATO take a firmer role vis-à-vis possible future Russian threats to their national security. In response, NATO leaders expanded confrontational rhetoric with respect to Russia and proposed that additional military forces be stationed on a rotating basis in these countries. In a sense, the events in Ukraine in 2014, like occupation by the Red Army after World War II, acted as a catalyst bringing the former East Bloc countries closer in terms of identity to the rest of Europe. However, how this continues to play out is difficult to discern, given that events since 2008 have been fluid and, as of this writing, remain clouded and uncertain. We can only conclude that identities, politics, and a sense of self and place in 'East Europe' might remain the same – troubled and ambiguous – or might be clarified in the years to come, depending on whether Cold War I or Détente II results from events further east from Warsaw and Bratislava, and on how the European Union and its central bank respond to the continuing sluggish recovery and unequal distribution of capital and status in economic decision making.

Eating Disorders

Rebecca J Lester, Washington University, St. Louis, MO, USA

Abstract

Eating disorders are complex biopsychosocial conditions that can be fatal if left untreated. Often considered to be products of modern Western societies, syndromes resembling eating disorders have been documented across the globe for thousands of years. This article examines current clinical understandings of eating disorders (including diagnosis, prevalence, etiology, and treatment) as one particular lens on phenomena that appear to be much more broadly distributed than previously thought, raising important questions about the relationships between culture and epistemology. After reviewing the historical development of the diagnostic categories of eating disorders, it then discusses the current classification system for these conditions. The next section examines the cross-cultural data on eating disorders and arguments regarding the role of acculturation in the development of these conditions. The last section discusses the treatment of eating disorders from a clinical perspective.

Diagnostic Criteria as Cultural Models

Eating disorders – Anorexia Nervosa (AN), Bulimia Nervosa (BN), Binge Eating Disorder (BED), and Eating Disorder Not Otherwise Specified (EDNOS) – are western psychiatric categories for complex, biopsychosocial conditions in which individuals feel compelled to engage in eating behaviors that can be fatal if left unaddressed. They also entail disturbances in self-perception and severe emotional, psychological, and interpersonal distress (American Psychiatric Association, 2013). Long theorized by clinicians and social scientists to be products of modern western culture and capitalist modes of commodification (e.g., Prince, 1985; Bordo, 2004), conditions that look very much like eating disorders have been identified in the historical and cross-cultural literature (e.g., Bynum, 1987; Miller and Pumariega, 2001) leading scholars to begin to question these assumptions (Keel and Klump, 2003). Accepting or refusing food, though the meanings of all the restriction of food and eating to the point of physical compromise or even death in pursuit of social, moral, or spiritual ends, is by no means unique to the postindustrialized West, though the specific understandings of such behaviors may be different than what we today associate with these conditions. Such concerns are highly culturally informed, and are also inflected by gender, age, ethnicity, and specific life events and relationships. For this reason, patterning of such behaviors can become evident, particularly in contexts where they have been marked as a recognizable state or condition, producing a looping effect (Hacking, 1986). It is, however, a mistake to take one such cultural and historical patterning as isometric with the condition itself, with other patternings mere reflections of its more authentic expression. Eating disorders as they are currently understood in Western psychiatric classification are more appropriately viewed as one possible articulation of a set of concerns that can assume different forms of expression in different contexts.

Historical Accounts of Disordered Eating

Unusual eating practices and elaborate meaning systems to account for these behaviors are not unique to contemporary Western culture. Throughout recorded history, syndromes involving unusual food behaviors – coupled with culturally meaningful preoccupations about body, self, and social perception – have emerged, peaked, and dissipated.

One of these peaks occurred in medieval Europe. During the twelfth through fifteenth centuries, increasing numbers of Catholic women religious gained widespread notoriety for their extreme food asceticism and other ascetic body practices. Similar to people diagnosed with AN and BN today, these women (including such figures as Theresa of Avila and Catherine of Sienna) reportedly ate very tiny amounts of food or refused to eat at all, eventually living on no sustenance but the Eucharist for months or even years at a time (Bynum, 1987; Schleif and Schier, 2009; Mueller, 2010). When urged to eat by others they would refuse, citing desires to share in Christ's suffering by denying themselves food and other bodily comforts. If forced to eat by superiors, some would steal off afterward and induce vomiting. These fasting nuns claimed that, through their self-induced suffering, they were able to achieve direct communication and communion with Christ. While aspects of these reports were likely exaggerated by hagiographic chroniclers, significant evidence does exist from the journals of these women and their confessors to substantiate that their eating habits were austere in the extreme and were considered highly unusual and even bizarre by local standards.

Ascetic movements during the same period were not confined to Christianity, but also emerged in Hindu, Buddhist, Jain, Jewish, and Muslim communities, with some ascetic traditions evident significantly earlier than the Middle Ages (Kaelber, 2006). This suggests that the practice of purposefully denying oneself necessary nourishment as a means of spiritual, social, and/or personal transformation is not proprietary to one specific culture or religious doctrine, and may instead reflect a common human strategy of meaning making.

Another significant peak in reports of eating disturbances occurred in the nineteenth century. Across Europe and North America, reports of 'miraculous maids' or 'fasting girls' began to emerge. These young women, most from rural areas and generally between the ages of 13 and 20, gained notoriety for

their ability to remain alive despite a refusal to eat. Many came to enjoy a sort of celebrity status for their fasting, with their names and photographs appearing regularly in newspapers around the country. The attention and gifts showered upon these girls and their families as a result of this notoriety led some to become suspicious of the motivations of the girls' fasting behaviors. In some cases, medical doctors were called in to perform rigorous examinations of the girls to determine the veracity of their claims. In at least one instance, this resulted in the girl's death. The phenomenon of the 'fasting girls' was thought to be a form of hysteria, and subsided shortly after Gull and Lesegue first 'discovered' anorexia nervosa (Brumberg, 2000).

Other accounts of eating disturbances that have behavioral similarities to current eating disorders can be found as far afield as seventeenth-century Japan (*fushokubyo*, or 'non-eating illness', was prevalent among women and the condition was thought to have a psychological origin), early dynastic China (where medical scrolls describe ailments very similar to anorexia and bulimia), and in the tribal lore of parts of Africa. The clinical and scholarly perception that eating disorders are a modern Western phenomenon, then, may be due as much to the professionalization of Western medicine as a discipline and the emergence of specialized fields within it, as with the emergence of a fundamentally new syndrome uniquely produced by the cultural conditions of the industrialized West.

AN was one of the earliest conditions to fall under the special purview of the emergent field of professional psychiatry. Defined as a distinct clinical condition in 1863 by British physician William Gull (and independently around the same time by Lesegue in France), a hallmark of this condition was, specifically, the 'nervosa' aspect of it, the fact that no physiological cause could be identified for the lack of appetite or refusal to eat. In later years, such behavior and associated thoughts and feelings about food, body, sex, relationships, and morality became covered with the broader umbrella of hysteria (of which AN was considered to be a specific articulation). What we now call bulimia nervosa BN was generally considered to be part of the AN syndrome and was not recognized as a separate diagnosis (Brumberg, 2000).

As the field of psychiatry developed and sought legitimacy within the medical community, standardized diagnostic frameworks emerged, most notably the Diagnostic and Statistical Manual of Mental Disorders (DSM), whose first edition was published in 1952. Now in its fifth edition, the DSM is the compendium of criteria by which mental health practitioners in the United States (and, increasingly, around the globe) identify, diagnose, and treat psychiatric conditions. AN appeared in the first edition of the DSM and, although the notion of hysteria had largely fallen out of favor by that time, many of understandings of the condition, assumptions about its etiology and epidemiology, and views of treatment that developed during the hysteria years persisted in the new psychiatric nosology, eventually being so embedded in how we built knowledge about the condition as to be naturalized in our current approaches (Brumberg, 2000). In 1979, with the publication of the DSM-III, BN was identified as a separate clinical condition to AN; its diagnostic criteria have also undergone significant revisions since then. BED was first identified in the clinical literature in 1959, but was not included in the DSM until the most recent version, the DSM-V, published in 2014. EDNOS is a category used to capture disordered eating that does not meet the strict diagnostic criteria of AN, BN, or BED.

Current Western diagnostic criteria for eating disorders, then, have emerged from over 150 years of Western clinical practice and research. They have been honed and refined in order to capture with increasing specificity what are believed by psychiatrists to be the behavioral, psychological, medical, and social dimensions of these complex illnesses, based on the specific cases available to them for investigation and treatment. As such, they are cultural models emanating from Western psychiatry.

Anthropologists and other social scientists have argued persuasively that the DSM is not a culture-free scientific document, but instead articulates a particular modern Western ethnopsychology that values self-mastery, emotional regulation, and autonomy (e.g., Gaines, 1992; Kirmayer, 2007). This view has been further developed by cross-cultural researchers investigating issues related to psychic and emotional distress (Guarnaccia and Rogler, 1999; Kirmayer, 2001; Kleinman, 1988; Hinton and Good, 2009). While DSM behavioral criteria may be imposed on conditions of distress in other contexts, the meanings, motivations, and experiences of these behaviors may be radically different from those reported by North American subjects, upon whose illness expressions the criteria are based. Similarly, DSM criteria may miss important features and associated practices, beliefs, and experiences that are central to the condition in other contexts but not considered relevant for DSM diagnosis. Taken together, this significant body of research demonstrates that current DSM definitions of mental disorders (including eating disorders) are strongly culturally informed, reflect the social conditions and cultural concerns of late twentieth and early twenty-first-century North America, and may not be seamlessly generalizable to other contexts.

Nevertheless, the conditions described in the DSM are not entirely arbitrary. While they may not describe universal disease conditions, they do describe *something*, and those descriptions carry epistemological and practical weight for clinicians, researchers, and individuals themselves who fall into these diagnostic categories. They also attempt to capture the very real suffering of people whose lives have become unbearable. However culturally laden these categories are, what they strive to articulate is based on the experiences of thousands of people who have presented with similar symptom patterns. While we cannot take these experiences to be representative of all individuals, to dismiss them would be similarly discounting of those upon whom these categories have been based.

Current Diagnostic Categories

Anorexia Nervosa

The core diagnostic features of AN according to the DSM V are that the individual (1) restricts caloric intake leading do significantly low body weight (generally considered to be 85% below

ideal body weight for age, sex, and height), (2) has either an intense fear of gaining weight or of becoming fat, or persistent behavior that interferes with weight gain (even though significantly low weight); and (3) shows a disturbance in the way one's body weight or shape is experienced, undue influence of body shape and weight on self-evaluation, or persistent lack of recognition of the seriousness of the current low body weight (American Psychiatric Association, 2013). Amenorrhea in postmenarcheal females was a diagnostic criterion for AN in previous versions of the DSM IV but has been removed in the DSM V, as it did not apply to postmenopausal women, women on oral contraceptives that interrupt the menstrual cycle, or males (**Table 1**).

The current diagnostic model subdivides AN into two subtypes: restricting type and binge-eating/purging Type. In the restricting type, individuals restrict food intake and do not engage in any kind of bingeing or compensatory behavior, such as purging, laxative use, or excessive exercise. In the binge-eating/purging type, individuals regularly engage in either bingeing or purging (or both) during the current episode of anorexia. They are not considered bulimic primarily because of their low weight (below 85% of ideal body weight or IBW) (American Psychiatric Association, 2013).

Individuals with AN frequently exhibit symptoms of low mood, difficulty sleeping, hopelessness, guilt, restlessness, social withdrawal, irritability, and difficulty concentrating, all of which are consistent with the symptoms of Major Depressive Disorder. It is not always clear whether these features indicate an underlying mood disorder, or whether they are the effects of starvation itself. The metabolic changes associated with the early phases of the illness may actually ameliorate the depressive symptoms (e.g., individuals may feel increased energy, increased confidence, a sense of focus and purpose), thereby reinforcing the behaviors. Over time, however, the starvation process loses its mood-elevating effects and, instead, exacerbates (and perhaps amplifies many times over) underlying mood difficulties (Kaye, 2008; Russell, 2013).

Table 1 DSM Criteria for AN

Diagnostic criteria for anorexia nervosa
1.Refusal to maintain body weight at or above a minimally normal weight for age and height (e.g., weight loss leading to maintenance of body weight less than 85% of that expected; or failure to make expected weight gain during period of growth, leading to body weight less than 85% of that expected).
2.Intense fear of gaining weight or becoming fat, even though underweight.
3.Disturbance in the way in which one's body weight or shape is experienced, undue influence of body weight or shape on self-evaluation, or denial of the seriousness of the current low body weight.
4.In postmenarcheal females, amenorrhea, i.e., the absence of at least three consecutive menstrual cycles. (A woman is considered to have amenorrhea if her periods occur only following hormone, e.g., estrogen, administration.)
Specify type
1.Restricting type: During the current episode of anorexia nervosa, the person has not regularly engaged in binge-eating or purging behavior (i.e., self-induced vomiting or the misuse of laxatives, diuretics, or enemas).
2.Binge-eating/Purging type: During the current episode of anorexia nervosa, the person has regularly engaged in binge-eating or purging behavior (i.e., self-induced vomiting or the misuse of laxatives, diuretics, or enemas).

Many individuals with AN have obsessive (pressured) thoughts and/or compulsive (pressured) behaviors, which often extend beyond food and body alone; for example, obsessions about contamination or compulsions about cleaning or symmetry are common. Other common features related to AN include fear or anxiety about eating in front of others, an obsessive focus on clothing sizes (the size '00' is often a coveted goal), perfectionism in all areas of life, inhibited emotional expression, and deep feelings of shame and self-loathing (Lavender et al., 2013; American Psychiatric Association, 2013; Phillips and Kaye, 2011).

AN carries a number of potential risks, as extreme starvation can damage the major organ systems of the body as well as generating a great deal of collateral damage. Leukopenia (low white cell count in the blood) and anemia (low red cell count) are common. Dehydration can lead to elevated blood urea nitrogen (BUN), indicating potential liver damage. Low magnesium and zinc levels are frequently seen in AN patients, attesting to the body's depletion of essential minerals. Elevated levels of amylase may indicate serious pancreatic dysfunction. Females with AN often have low estrogen levels as a result of the illness, whereas males with AN tend to have lowered testosterone levels. Bradycardia (low heart rate) and arrhythmias (irregular heat beats) can result from AN, as can a reduction in brain volume. If purging, laxative use, or fluid restriction are part of a client's profile, serious electrolyte imbalances can occur which may lead to heart attack and death (Mehler and Anderson, 2010; Trent et al., 2013).

AN as a full-blown illness is rarely diagnosed before puberty, although many associated features may be present in people as young as 3–5 years old (e.g., concern about being 'fat', restriction of food intake, counting calories). Historically, AN has been documented primarily among white, upper-middle class Caucasian women of West European or North American descent living in industrialized countries. A review of the clinical, historical, epidemiological, and ethnographic literature, however, brings into question these features as being central to the illness itself, suggesting that this stereotype of the 'typical' anorexic patient may reflect sampling bias (e.g., Grilo et al., 2005). Recent community-based studies reveal that AN is present among nonwhite (Regan and Cachelin, 2006; Striegel-Moore et al., 2003; Dohm et al., 2010), nonaffluent (e.g., Rogers et al., 1997), and non-Western (e.g., Malson and Nasser, 2009) populations, and that rates among males women over 40 and males seem to be increasing in recent years (Smink et al., 2012). Whether such findings reflect a shift in the epidemiology of anorexia or changes in diagnostic practices (or both) is unclear; regardless, the stereotype of anorexia as a disease of affluent white Western women no longer holds up.

The incidence rate of AN among females has recently been found to be between 8 and 13 cases per 100 000 persons per year, and the prevalence rate is approximately 0.3% using strict diagnostic criteria (Bulik et al., 2005). AN is therefore more common than autism (Fombonne, 2005). Individuals with a first-degree relative with AN have an increased risk of developing the disorder themselves. Studies of monozygotic twins indicate a significantly higher concordance rate for AN than dizygotic twins, suggesting a strong genetic substrate to

the illness (e.g., Lock and Le Grange, 2011). It remains unclear, however, the degree to which environmental and social factors contribute to these findings.

Typically beginning in adolescence, AN often follows a cyclical pattern of exacerbation and remission which can extend across the life course. With proper treatment, an estimated 50% of individuals with AN recover fully, 33% improve somewhat, and 20% remain chronically ill (Steinhausen, 2002). The mortality rate among people with anorexia has been estimated at 0.56% per year, or approximately 5.6% per decade, which is about 12 times higher than the annual death rate due to all causes of death among females aged between 15 and 24 in the general population (Sullivan, 1995). Perhaps not surprisingly, then, AN has the highest mortality rate of any mental illness (Arcelus et al., 2011).

Bulimia Nervosa

BN is characterized by episodes of binge eating (defined as consuming a large amount of food in a short amount of time, accompanied by a sense of lack of control over eating) followed by compensatory behavior such as self-induced vomiting, excessive exercise, misuse of laxatives or other medications (such as amphetamines) or fasting aimed at 'undoing' the binge in order to prevent weight gain. To meet the criteria for BN, this pairing of bingeing and compensatory behavior must occur, on average, at least twice a week for 3 months. The individual's self-evaluation must also evidence an extreme concern with issues related to body weight and shape (**Table 2**).

Table 2 DSM Criteria for BN

Diagnostic criteria for bulimia nervosa

1.Recurrent episodes of binge eating. An episode of binge eating is characterized by both of the following:

a. Eating, in a discrete period of time (e.g., within any 2-h period), an amount of food that is definitely larger than most people would eat during a similar period of time and under similar circumstances.

b. A sense of lack of control over eating during the episode (e.g., a feeling that one cannot stop eating or control what or how much one is eating).

2.Recurrent inappropriate compensatory behavior in order to prevent weight gain, such as self-induced vomiting; misuse of laxatives, diuretics, enemas, or other medications; fasting; or excessive exercise.

3.The binge eating and inappropriate compensatory behaviors both occur, on average, at least twice a week for 3 months.

4.Self-evaluation is unduly influenced by body shape and weight.

5.The disturbance does not occur exclusively during episodes of Anorexia Nervosa.

Specify type

1.Purging type: During the current episode of bulimia nervosa, the person has regularly engaged in self-induced vomiting or the misuse of laxatives, diuretics, or enemas.

2.Nonpurging type: During the current episode of bulimia nervosa, the person has used other inappropriate compensatory behaviors, such as fasting or excessive exercise, but has not regularly engaged in self-induced vomiting or the misuse of laxatives, diuretics, or enemas.

Often, for individuals with bulimia, binge foods are those deemed 'bad' – salty foods, fats, or sweets. Bulimics might binge and purge up to 10 or 12 h each day. They may take 10, 15, or even 20 laxatives or exercise for 4 h each evening. The shame that accompanies bulimic behaviors fuels a cycle of self-loathing that keeps many sufferers from asking for help or wanting to admit they are struggling (Hackler et al., 2010).

Bulimia in the DSM V is subdivided into two types: purging type and nonpurging type. Purging type BN involves the active extraction of food/food derivatives from the body through such things as vomiting, laxative abuse, and the use of diuretics and enemas. Nonpurging type BN entails compensatory behaviors such as fasting or excessive exercise that do not entail these evacuations. In both subtypes, however, compensatory behaviors meant to offset the caloric intake during binges are present.

Unlike individuals with AN, those with BN tend to be of relatively normal weight. Mood disturbances such as depressed mood, low self-esteem, and hopelessness are common in BN and, as with AN, often predate the onset of the eating disturbance. Anxiety symptoms such as obsessive worry and fear of social situations may also be elevated in individuals diagnosed with BN. Substance abuse in BN appears quite high and may be linked to the desire to control weight (e.g., stimulant abuse) or perhaps modulate mood (e.g., alcohol abuse) (Baker et al., 2010).

Frequent purging of any kind can produce significant electrolyte imbalances (specifically, low potassium, low sodium, and low chloride), which can endanger cardiac function. Recurrent vomiting can also erode the teeth causing cavities, breakage, and discoloration. It can also cause the salivary glands to become visibly enlarged. In some cases, esophageal tears and gastric rupture can occur, causing death. Individuals who abuse laxatives are at increased risk for gastrointestinal complications and may become dependent on laxatives to achieve normal bowel function (Mehler, 2011).

The lifetime prevalence of BN among women is estimated to be 1 to 3%, with the rate of males being approximately one-tenth of that number (Hudson et al., 2007). BN usually begins in late adolescence and often follows a period of caloric restriction or dieting. Like anorexia, recovery appears to occur in a cyclical pattern, with multiple periods of relapse interspersed with periods of improvement. Many individuals with BN continue to exhibit disordered eating or thoughts about food, body, and weight for many years after their overt symptoms subside.

BN, mood disorders, and substance use disorders are significantly increased among first-degree relatives of individuals with BN. As with AN, however, it is not clear from the data to what extent these correlations are due to genetic similarities vs social, environmental, and family systems factors. Similarly, like anorexia, BN has primarily been documented among young, middle-class Caucasian women of Western European or North American descent, but recent studies show notable rates among ethnic minorities in the United States and cross-culturally (e.g., Feinson, 2011), and significantly more research is needed on this topic.

Binge Eating Disorder

BED was first described in 1959 but will not officially be recognized as a distinct condition until its inclusion in the

DSM-5. The most common eating disorder in the United States, BED affects 3.5% of American women and 2% of American men (Hudson et al., 2007).

BED is characterized by recurrent episodes of bingeing and feeling a lack of control over eating, similar to BN. Additionally, the binges must include at least three of the following factors: eating rapidly; eating until uncomfortably full; eating large amounts when not hungry; eating alone out of embarrassment; or feeling disgusted, depressed, or guilty after eating. To meet diagnostic criteria for BED the individual must also feel marked distress about the bingeing and the behavior must occur at least twice a week for 6 months. Unlike BN, in BED no forms of purging are present.

People who are obese and suffer from BED are at significantly increased risk for several potentially life-threatening complications, including heart disease, high blood pressure, type 2 diabetes, sleep apnea, high cholesterol, gall bladder disease, and certain types of cancer (Bulik and Reichborn-Kjennerud, 2003). Due to its recent inclusion as an official DSM diagnosis, research to determine the associated disorders, risk factors, and social, age, and gender features of BED is in its infancy but is vigorously underway.

Eating Disorder Not Otherwise Specified

EDNOS category is used to identify disordered eating that does not meet the full criteria for AN, BN, or BED. EDNOS has been shown to be equally as dangerous as these other disorders, and more than 50% of all diagnosed eating disorders in the United States all into the EDNOS category (Fairburn et al., 2007). It is regular practice in the United States for insurance companies to exclude EDNOS from treatment coverage, in part because its variability in presentation precludes systematic treatment studies.

Cross-Cultural Studies of Disordered Eating Disorders

Syndromes consistent with the DSM criteria for eating disorders have been widely documented outside of the United States and Europe, from Egypt to China, to Fiji, and beyond. A robust literature on cultural, socioeconomic, racial, ethnic, and acculturation influences on eating disorders has grappled with questions of whether, how, and to what degree Western culture is a necessary, if not sufficient, condition for the emergence of eating disorders (Soh et al., 2006). In teasing out the relationships between culture and eating disturbances, researchers have focused on questions of cultural change, acculturation, and motivating constructs.

For example, syndromes that have behavioral overlap with eating disorders may, in fact, be motivated by entirely different concerns than a drive for thinness (as in Japan, where the prevailing concern is modesty, not thinness (Pike and Borovoy, 2004)) or may reflect material realities rather than psychological pathology (as in South Africa, where the behaviors of women found to meet diagnostic criteria for BN were found, upon further investigation, to be due to the scarcity and unpredictability of food availability and the frequent contamination of meat (LeGrange et al., 2004)). Similarly, as Anderson-Fye (2004) has persuasively demonstrated in Belize, local engagements with supposedly eating-disorder-producing cultural change are not passive but are actively negotiated, sometimes producing unexpected outcomes of body confidence and resilience. The relationship between contemporary Western psychiatric understandings of eating disturbances and historical and cross-cultural accounts of similar conditions is complex, raising significant questions about how to best conceptualize these syndromes and how to best respond to them.

Studies of eating disturbances among minority populations within Western countries have produced mixed findings. Some differences have been found in terms of which eating disorder is most prevalent among a particular group, or which beliefs and behaviors seem to be the most elaborated, but most studies conclude there is no significant difference in eating disorders across ethnic groups in Western contexts. Similarly, early studies of eating disorders among immigrants and first-generation individuals suggested that a high degree of acculturation to Western values was associated with higher rates of eating disorders. However, more recent studies have demonstrated that level of acculturation makes little difference in risk for eating disturbances and, in some cases acculturation may in fact reduce the risk of eating disturbances (Levine and Smolak, 2010).

Eating Disorders and Cultures in Transition

Another perspective on the role of culture in eating disorders holds that it is not Western culture per se that causes eating disorders; rather, it is the condition of experiencing and living within the difference *between* two cultures that generates risk. Specifically, it is thought that the mismatch between a so-called 'traditional' culture and an adopted (i.e., Western) culture may increase the likelihood of body image disturbances in some individuals, putting them at risk for developing an eating disorder. As Anderson-Fye (2004) has demonstrated, however, cultural change need not always produce a sense of crisis, especially among adolescents. Furthermore, she argues, we must be careful when generalizing about responses to this change, as historical, economic, and cultural factors particular to a given locale will significantly shape how cultural difference is experienced and understood.

Motivating Constructs in Eating Disorders

A key diagnostic feature of eating disorders as defined in the DSM is "an intense fear of gaining weight or becoming fat" (American Psychiatric Association, 2013). While fat phobia is associated with eating disturbances in Western and Western-influenced societies, this is by no means universal. Cross-culturally, syndromes that otherwise meet the behavioral criteria of the DSM do not always contain this component, with motivations for self-starvation ranging from modesty to religious motivations, to gastrointestinal complaints. This finding suggests that the DSM criteria may capture one particular expression of a condition that may manifest in different ways depending on cultural context. A growing number of researchers support the development of a category

of 'nonfat-phobic anorexia' (NFP-AN) in order to capture this diversity (Becker et al., 2009).

Treatments for Eating Disorders

The relationship between contemporary Western psychiatric understandings of eating disturbances and historical and cross-cultural accounts of similar conditions is complex, raising significant questions about how to best conceptualize these syndromes and how to best respond to them. Current treatment models have been developed within contexts saturated with Western cultural systems, values, and conceptual categories (Gremillion, 2003), based on knowledge gathered primarily from clinical populations; that is, individuals who have come to the attention of the medical community, been diagnosed in a certain way, and have the resources to obtain specialized care. Given this, it would seem reasonable to suspect that prevailing definitions, psychological correlates, and age/gender features of eating disorders based on a very narrow demographic may not be seamlessly generalizable to other populations. While this limitation does not undermine the value or validity of these findings for the contexts in which they were developed, it does raise serious concerns about their applicability in other populations and in other cultural settings.

In recent years, major strides have been made by clinicians in the United Sates and Europe to develop, evaluate and disseminate effective, evidence-based interventions for eating disorders and to outline standards of care. Cognitive-Behavioral Therapy (CBT), Interpersonal Therapy (IPT), and Dialectical-Behavioral Therapy (DBT) have been shown to be effective in treating BN and BED in adults (Wilson and Shafran, 2005), and family-based therapy (FBT) appears to be effective in treating AN and BN in children and adolescents (Lock and Le Grange, 2012). Having access to a full spectrum of care – inpatient hospital-based care, residential treatment, and outpatient therapy – and treatment that is consistent with current American Psychiatric Association guidelines has been shown to be critical for the successful treatment of eating disorders (Wilson and Shafran, 2005). The current high mortality and morbidity rates associated with eating disorders may be due in significant part to the difficulties individuals face in accessing and obtaining appropriate and complete treatment (Silber and Robb, 2002).

However, it is not clear that this is the best course of treatment for eating disorders or eating-disorder-like conditions in other cultural contexts, nor is it clear that the therapeutical approaches found to be successful in the United States will be similarly helpful elsewhere. Syndromes that have behavioral overlap with eating disorders may, in fact, be motivated by entirely different concerns than a drive for thinness, or may reflect material realities rather than psychological pathology. Lester (2007), for example, found that, despite the use of a common therapeutic language, eating disorder clinicians in Mexico City rejected American interpretations of the core causes of eating disorders, and found American treatment approaches to be harmful rather than helpful. In other words, the development of diverse treatment approaches for eating disorders is lagging far behind the recognition of the diversity of populations who struggle with these conditions.

Conclusion

Eating disorders and similar conditions continue to intrigue researchers, practitioners, academics, and the general public alike. Current research suggests that the DSM criteria for these conditions capture particular cultural expressions of a phenomenon that has existed throughout history and cross-culturally in different forms. Additional research is needed to continue to tease apart the relationships among culture, practice, interpersonal, and subjective experiences that facilitate the use of self-starvation and other harmful eating disturbances as patterned responses to distress.

Whatever the cultural construction of Western diagnostic categories, it is critical to remember that they do capture, however partially and imperfectly, real suffering in the world. The conditions currently called eating disorders generate enormous distress for individuals who manifest them and those who care for them. They cause severe medical, psychological, and social compromise, and they can be lethal. Examining the cultural dimensions of these conditions and their definitions does not negate the fact that real suffering exists; it merely reminds us of the imperative to continually examine the cultural assumptions embedded in prevailing regimes of knowledge so that we can better understand and respond to this suffering.

Eco-cities and Sustainable Urbanism

Simon Joss, University of Westminster, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The 'eco-city,' and related concepts and practices of 'sustainable urbanism,' have since the early 2000s gained growing international popularity and entered mainstream policy as a consequence of the forceful combination of global climate change concerns and a rapidly urbanizing world population. Sustainable urbanism engages with various aspects of environmental, economic, and social sustainability concerning the urban context. Eco-cities are initiatives that variably promote and pursue sustainable development in relation to urban infrastructure, services, and community at district, town, or metropolitan levels. Governance challenges involved include effective coordination of innovation, planning, and development across policy sectors; integration across urban scales; and engagement with stakeholders and communities. The need for global sustainable city frameworks and standards becomes more apparent as both the number of practical initiatives and international cooperation increase.

Introduction

A growing interest in the 'eco-city' – and similar concepts, such as the 'sustainable city,' 'smart city,' 'low-carbon city,' and 'resilient city' – has been matched, since the early 2000s, with the significant global proliferation of a diverse range of related policies and practical initiatives. Recent activity has been particularly notable across Asia, in addition to Europe and North America, from where the eco-city concept first originated in the 1970s and 1980s. Key driving factors behind this development include climate change policy, accelerated urbanization, and globalization processes, which together have placed cities center stage.

The 'eco-city' may be best understood as an umbrella term that covers various notions of, and approaches to, sustainable urbanism, rather than a conceptually coherent and practically uniform phenomenon. It brings together multiple forms of sustainable development (SD) applied at different urban scales and locally contextualized, from 'retrofitting' entire cities to building new 'smart-green' urban neighborhoods, and from focusing on environmental innovations to promoting socio-economic measures. It further brings together diverse actors in often new governance relationships: municipal authorities, national governments, technology firms, international consultants, nongovernmental organizations, and citizens. Nevertheless, underlying this diversity, a few core conceptual and ideological perspectives variably manifest themselves. These include the 'triple bottom line' of sustainability, ecological modernization, and scientific-technological innovation that, together, characterize contemporary eco-city and related sustainable urbanism discourses.

The global popularity of eco-cities of various kinds prompts the need to bring this recent urban planning paradigm into question both conceptually and practically, by inquiring into underlying normative assumptions, comparing various policy and practical approaches, and critically analyzing outcomes. This seems particularly important given the eco-city's relatively untested promise of reconciling environmental protection with urban economic growth.

Eco-City Dimensions

There are currently no standard, internationally applied definitions of what an 'eco-city' is and what constitutes 'sustainable urbanism.' At one level, this is not surprising, given the diversity of concepts and practices set within particular local settings and traditions, and the competition among the various actors involved. At another level, however, this risks rendering eco-city initiatives conceptually vacuous – especially where they are deployed for promotional purposes – as well as undermining (international) comparability and replicability. From an innovation studies perspective, the current phase may be seen as experimental, to be followed by a phase of consolidation that over time may be expected to lead to more established international norms and accepted 'good practice.' Already, several governmental, nongovernmental, and private organizations are vying to define global eco-city standards and frameworks (Joss et al., 2012; Joss, 2012).

Apart from underlying conceptual differences and context-specific characteristics, a further reason why commonly agreed definitions are hard to come by is that the eco-city is inherently future-oriented: while it sets itself clearly apart from the conditions and experience of (most) current cities – striving to become less polluting, low-carbon, economically resilient, and more livable – its precise form and nature remain as yet invisible in the indeterminate future. As Richard Register (1987: 3), one of the originators of the modern eco-city movement, aptly noted in his original work *Ecocity Berkeley: Building Cities for a Healthy Future*: "The eco-city is an ecological city. No such city exists."

Still, at a general level, several (aspirational) sets of 'eco-city dimensions' – as sometimes referred to in the literature – can be discerned (see, e.g., Girardet, 1999; Joss, 2011a; Kenworthy, 2006; Lehmann, 2010; Register, 2006; Roseland, 1997/2012; Wheeler and Beatley, 2004). As noted in this article, these elements of sustainable urbanism are not applied equally across initiatives. Some initiatives are characterized by an explicit focus on a limited number of key goals – say, carbon-neutral, renewable-energy urban developments – while others deliberately emphasize a broader, multidimensional approach.

One overarching definition of the eco-city is that of 'an ecological city as economic city,' as illustrated by the World Bank's *Eco² City* initiative (World Bank, 2010). Here, following the concept of ecological modernization, ecological and economic objectives are seen as intertwined and mutually dependent. Other definitions, closely aligned with the concept of SD, emphasize the social dimension of the eco-city – with reference to issues of social justice, equity, well-being, participatory governance, and so on – alongside ecological and economic dimensions. In such cases, the term 'sustainable city' tends to be to the fore.

Sustainability 'Triple Bottom Line' in the Urban Context

Eco-city dimensions may be usefully categorized in terms of the 'triple bottom line' of sustainability (environmental, economic, and social), complemented by city-specific dimensions, including urban design, systems, and governance. Table 1 lists prevalent eco-city dimensions along these categories.

At an individual level, these dimensions are typically specified in detail, with targets set in relation to current baselines and with particular time frames in mind. For example, China's Tangshan Caofeidian International Eco-city, under construction since 2009, defines these dimensions through a set of 141 'eco-city indicators' (Joss and Molella, 2013). This includes, among others, targets for 95% energy demand to be met from on-site renewable energy sources; 60% overall waste recycling, with less than 10% waste going to landfill; and – reflecting current levels of water pollution and water scarcity – some 20 targets for water preservation and recycling. Sixty eight of the indicators apply to the city as a whole, with 16 operating at neighborhood, and 25 at site levels.

Another example, *Greenest City: 2020 Action Plan* (City of Vancouver, 2010), includes 10 high-level dimensions (Table 2). Each dimension is further defined through one to two key targets or indicators (some quantitative and others qualitative) set against specified baselines and including strategic action plans. Following in the footsteps of its earlier *EcoDensity Charter* (unveiled in 2008 under the slogan 'envisioning the eco-city'), the City of Vancouver launched 'Greenest City' in 2010 as a flagship initiative aimed at propelling the city to 'most sustainable city' status worldwide by 2020.

Types of Urban Development

Eco-city dimensions can also be defined in relation to the types of urban development (Joss, 2011a; all examples of eco-city initiatives mentioned here and throughout the article are referenced in Joss et al., 2011). A useful distinction can be made between (1) new developments – that is, entire urban centers built from scratch, such as Masdar (United Arab Emirates (UAE)), the self-proclaimed world's first zero-carbon,

Table 1 Eco-city dimensions: general dimensions and related targets, based on a sustainability 'triple bottom line' applied to the urban context

Environmental sustainability	CO_2/GHG	Reducing GHG emissions/energy consumption; promoting renewable energy generation
	Buildings	Reducing energy use; promoting carbon-neutral buildings
	Water	Reducing water consumption; improving water recycling
	Transport	Promoting integrated public transport
	Waste	Reducing waste; increasing waste recycling and waste-to-energy generation
	Biodiversity	Protecting green spaces; promoting biodiversity
Economic sustainability	High-skilled, 'green' jobs and employability	Investing in the knowledge economy; attracting 'green' business
	Competitiveness and resilience	Enhancing international competitiveness; promoting community self-reliance
	Smart technology	Promoting 'smart' technological innovation
	Well-being	Improving individual and social well-being
	Housing	Providing affordable housing and mixed usage
	Urban agriculture	Promoting urban agriculture and local food networks
Social sustainability	Livability	Creating socially inclusive, vibrant communities
	Equity	Fostering equity within and between generations
	Civic engagement	Encouraging participation in public life
	Cultural diversity	Promoting cultural engagement and diversity
Urban design and systems	Compactness	Increasing density of housing, along transport arteries
	Scale	Improving integration across neighborhood, district, city, and regional levels
	Ecosystems management	Improving information management of urban infrastructure and systems (water, energy, etc.)
Urban governance	Policy coordination	Enhancing multilevel policy coordination
	Public–private partnerships	Promoting partnerships involving public, private, and nongovernmental actors
	Political accountability	Ensuring transparency, openness, and participation; collaborative planning

CO_2: carbon dioxide; GHG: greenhouse gas.

Table 2 Vancouver's Greenest City 2020 dimensions and indicators

Eco-city dimension	*Indicators or targets*	
1. Green economy	Double the number of green jobs (over 2010 levels) by 2020	Double the number of companies actively engaged in greening operations (over 2011 levels) by 2020
2. Climate leadership	Reduce GHG emissions produced by residents by 33% from 2007 levels	
3. Green buildings	Require all buildings constructed in 2020 and later to be carbon neutral in operation	Reduce energy use and GHG emissions in existing buildings by 20% over 2007 levels
4. Green transportation	Over 50% of trips to be by foot, bicycle, and public transport	Reduce average distance driven per resident by 20% from 2007 levels
5. Zero waste	Reduce the solid waste going to the landfill or incinerator by 50% from 2008 levels	
6. Access to nature	All Vancouver residents to live within a 5-minute walk of green open space by 2020	Plant 150 000 new trees by 2020
7. Lighter footprint	Reduce Vancouver's ecological footprint by 33% over 2006 levels	
8. Clean water	Meet or beat the strongest of British Columbian, Canadian, and appropriate international drinking water quality standards and guidelines	Reduce per capita water consumption by 33% from 2006 levels
9. Clean air	Always meet or beat the most stringent air quality guidelines from Metro Vancouver, British Columbia, Canada, and WHO	
10. Local food	Increase city-wide and neighborhood food assets by a minimum of 50% over 2010 levels	

GHG: greenhouse gas; WHO: World Health Organization.

zero-waste new city, whose initial phase was completed in 2010; (2) urban 'infill' developments, typically in the form of new neighborhoods or districts built on brownfield sites, such as 'Treasure Island' in San Francisco (USA); and (3) 'retrofit' developments aimed at regenerating and upgrading existing urban areas. The latter may take place at the district level, such as the 'Bo01' harbor district in the city of Malmö (Sweden), or at the city-wide level, as illustrated by Kawasaki, the first of a series of Japanese cities designated as 'eco-towns' by the national government. This distinction, too, underscores the diversity of the eco-city phenomenon: there is a significant difference (conceptual, physical, and technological) between entire, large-scale eco-cities built from scratch and eco-city innovation taking place within existing districts and towns.

Analytically, the eco-city can be usefully demarcated in relation to three overarching criteria: (1) scale – an eco-city refers to an urban sustainability development of significant scale in terms of area, infrastructure, and innovation concerned; (2) sectors – eco-city innovation typically takes place across sectors (land use, transport, energy, water, waste, housing, the public realm, etc.); and (3) policy – eco-city initiatives are underpinned by policy initiatives and processes (Joss, 2011a: 278–279). An eco-city initiative may be more or less significant, depending on the extent to which these criteria jointly apply. Concerning the issue of scale, a useful distinction can be made between intervention at the neighborhood, district, town or city, and urban-regional levels. From a planning perspective, ideally, integration should occur across these levels, 'from city to street' and 'from city to region.' This also underscores the importance of relevant governance structures (e.g., metropolitan government), policy processes (e.g., strategic plans), and planning tools (e.g., master plans) to support such multilevel and intersectoral coordination.

Defining and designing eco-city dimensions and sustainable urbanism features are in many ways challenging processes: first, they require a balancing act between tailoring these to the immediate local context – to achieve place-specificity – and making them more generally compatible with national and international policy and regulatory norms as well as replicable across individual sites. Second, it requires the integration of individual dimensions and indicators in order to avoid atomistic lists of goals and targets and to achieve an overarching interaction across urban systems and policy sectors. Third, the process should include transparent information about normative assumptions made and data sources used when defining eco-city dimensions, and about the subsequent capture, analysis, and assessment of data to measure progress toward agreed targets. Furthermore, the process relies on the input of multiple epistemic communities (engineers, planners, policy analysts, etc.) and stakeholder groups (developers, business organizations, nongovernmental organizations, residents, etc.), thus requiring effective coordination among diverse actors and the use of nonspecialist language. In other words, defining the eco-city is not just a technical exercise but also an intrinsically political and public process involving normative priorities, value judgments, and complex governance decisions.

Variations on a Theme

Different definitional emphases are often reflected in the category terms used to describe the phenomenon. Hence, the term 'eco-city' is sometimes used interchangeably with sister terms, such as 'biosphere eco-city,' 'climate-neutral city,' 'eco-garden city,' 'low-carbon city,' 'resilient city,' 'slim city,' 'smart city,'

'solar city,' and 'sustainable city' (Joss et al., 2013). While there is considerable overlap between these terms, it is nevertheless possible to discern underlying conceptual as well as practical differences: for example, 'low-carbon city' and 'solar city' initiatives are chiefly defined in terms of greenhouse gas (GHG) emission reduction strategies and related renewable energy generation, whereas 'smart city' initiatives emphasize the use of 'ubiquitous' technology – that is, the central use of information and communication technologies for digitally linking up and coordinating various urban systems in an overarching information system. Sometimes, the choice of terminology is because of national policy, as in the case of China, where the Ministry for Environmental Protection issued 'national standards for an eco-garden city' in 2004 in an attempt to regulate the fast-evolving eco-city development in the country (Joss and Molella, 2013). Here, as in other countries, including in particular Japan (Low, 2013), a normative connection with the 'garden city' a progenitor dating back to the early twentieth century, is deliberately created. UNESCO (2009), as an example of an international organization seeking to define the field, has opted for the term 'biosphere eco-city' as part of its *Man and the Biosphere* (MAB) program, originally launched in 1971; it emphasizes the relationship between urban centers and their surrounding regions (the hinterland) as a means of adequately capturing and addressing urban sustainability issues.

Global Developments

Eco-City Pioneers

The modern eco-city movement, and sustainable urbanism as a new genre in urban planning, can be traced back to the period of the late 1970s to early 1980s. In the United States, the Urban Ecology movement (active from 1975–85) was instrumental in generating ideas and debate leading to the publication of *Ecocity Berkeley: Building Cities for a Healthy Future* by Richard Register (1987). This seminal work built on publications during that period by academics and activists engaging with issues, such as compact cities (in response to the global oil and energy crisis of the 1970s), urban sprawl, mixed-use developments and integrated neighborhoods, urban agriculture ('the edible city'), and sustainable communities. It set out to redefine the city in ecological terms by, among others, relating it to its wider bioregion, integrating biodiversity in urban planning, addressing the problem of urban sprawl (and associated private transport), and arguing for more livable, pedestrian-friendly neighborhoods. In doing so, *Ecocity Berkeley* equally emphasized social and esthetic issues: it argued for the city as an 'instrument for human purpose' (Register, 1987: 13), creating fairness and opportunity for citizens, and for the importance of paying attention to esthetic considerations, including how urban spaces interrelate with the wider environment.

Elsewhere during this period, the prospect of creating an eco-city as "a human settlement of the future in which social and ecological processes are harmonized in the best possible way" was proposed theoretically by Yanitsky (1982: 470) in connection with the MAB program. (It was not until 2006, however, that UNESCO/MAB formally adopted its 'biosphere eco-city' as policy initiative.)

This early period was characterized by the emerging influence of environmental movements and policy and, relatedly, by increasing concerns about the declining environmental and socio-economic quality of cities. It was a pioneering phase, exploratory in nature and ideologically and politically often radical, bringing together activists, academics, and practitioners with a joint interest in developing alternative approaches to mainstream urban policy.

Practical initiatives were few and far between during this period: in the United States, apart from Register's eco-city project in Berkeley (California), Paolo Soleri's Arcosanti (Arizona) began life as an experimental town (with 50–150 inhabitants) seeking to combine architecture with ecology ('arcology'). In India, Auroville (1500 inhabitants) was promoted as a 'universal city in the making' based on ecologically and socially harmonious principles. At a significantly larger scale and increasingly recognized internationally, the cities of Curitiba, Brazil, and Freiburg, Germany, each began to develop strong urban sustainability legacies from the 1970s onward. In the case of Curitiba, this initially centered upon promoting integrated public transportation, against the background of rapid population growth and related urban sprawl. The city subsequently extended its efforts to, among other things, waste recycling, including a 'food-for recyclables' exchange system, and green urban spaces, as a means of enhancing the environmental, social, and cultural aspects of urban living. For its part, Freiburg gained a reputation in Germany, and more widely in Europe, as an 'ecological capital' following the adoption of a sustainable city master plan in 1986, its pioneering work on creating sustainable neighborhoods, and, in subsequent years, the adoption of a 'climate protection protocol' to cut GHG emissions. In both cases, political leadership proved pivotal in introducing and implementing urban sustainability measures as key elements of the cities' political and policy agenda: in Curitiba, the original driving force was Jamie Lerner, the city's mayor; in Freiburg, the impetus came from the city council.

Policy Mainstreaming

Sustainable urbanism and the sustainable city were given a significant boost during the 1990s in connection with the rise of SD to key national and international policy. Following the United Nations Environment Summit in 1992 in Rio de Janeiro, cities and communities around the world began to implement sustainability programs as part of the Local Agenda 21 initiative launched at this first 'Earth Summit.' Governments joined forces by launching national programs. In Sweden, for example, all local authorities and municipalities were required to implement Agenda 21 action plans, while in Germany, the small town of Schwabach was selected by the federal government for a pilot study to design a model for urban sustainability development to be emulated elsewhere in Germany. This second phase in global development can be seen as 'regulatory' in a dual sense: the eco-city became increasingly standardized through the concept and discourse of sustainability, while at the same time eco-city pilot initiatives

played a standardizing role in the formation of SD policy and related sustainable urbanism practice (Joss, 2011a: 268–270). Internationally, 1990 saw the launch of the International Council for Local Environmental Initiatives (ICLEI) as a global association dedicated to promoting SD and related Local Agenda 21 initiatives. Renamed ICLEI Local Governments for Sustainability in 2003, its membership includes over 1000 cities and towns worldwide.

Internationalization

The most significant growth in eco-city initiatives globally occurred in the most recent, third period, from the early to mid-2000s onward. According to a global census of eco-city initiatives, by the end of the decade, there were well over 170 eco-city initiatives (Joss et al., 2011). As **Figure 1** shows, this follows a steep increase in the launch of eco-city initiatives worldwide since the early 2000s, particularly since the mid-2000s. Characteristic of this third phase, then, was the concurrent globalization (in terms of geographical spread and international profile) and mainstreaming (in terms of policy uptake and practical implementation) of the eco-city phenomenon.

Growth was particularly pronounced in Asia and Australasia, where there have been several significant national programs since the early 2000s (for an overview, see special issue on pan-Asian eco-cities, *Journal of Urban Technology*, vol. 20, no. 1). For example, in 2001, the Indian government (Ministry of Environment and Forestry) launched a first eco-city program aimed at retrofitting six pilgrim cities (Kottayam, Puri, Thanjavur, Tirupati, Ujjain, and Vrindavan). This was followed in 2010 by the Ministry of Commerce and Industry's plans for four new-build eco-cities (Changodar, Dahej, Manesar Bawal, and Shendra) along the 'Delhi–Mumbai industrial corridor,' and in 2011 by the launch of a 'solar cities initiative' – including pilot projects in 36 cities – by the Ministry of New and Renewable Energy. In Japan, in 2009, the government selected 13 cities (Chiyoda, Iida, Kitakyushu, Kyoto, Minamata, Miyakojima, Obihiro, Sakai, Shimokawa, Toyama, Toyota, Yokohama, and Yusuhara) for eco-city development, following its earlier pilot program that saw Kawasaki named the first eco-town in 1997.

Arguably, developments have been most prolific in China, spearheaded at the national level by the Ministry of Environmental Protection (MEP), the Ministry of Housing and Urban–Rural Development (MOHURD), and the National Development and Reform Commission (NDRC), and enthusiastically pursued by provincial governments, municipal authorities, and private developers (Joss and Molella, 2013; see also **Box 1**). According to the World Bank (2009: ii), by 2009 an estimated 100 eco-city initiatives were underway in the country. A 2011 survey identified 259 cities above the prefecture level that had declared the intention of becoming an 'eco-city' or 'low-carbon city' (Chinese Society for Urban Studies, 2011: 27). Elsewhere across Asia and Australasia, notable eco-city programs were underway in South Korea (in Gwanggyo Ekonhill, Incheon Eco-city, Songdo International Business District, Magok/Seoul, and Sejong) and Australia (Sydney and Melbourne).

In Europe, the pioneers of sustainable urban development – including Almere (the Netherlands), Eko-Viikki (Helsinki, Finland), Freiburg (Germany), Linz (Austria), and Växjö (Sweden) – have been joined, since the early 2000s, by a larger group of existing cities and new developments where eco-city initiatives are taking place. These include Brøset (Trondheim/Norway), Clonburris (Dublin), Ecociudad Logroño (Montecorvo, Spain), Hamburg-Harburg (Germany), Hammerby Sjöstad (Stockholm, Sweden), and PlanIT Valley (Porto, Portugal). France is notable through its ÉcoCité initiative launched in 2008 that saw the selection of 19 cities across the country. The UK government launched an 'eco-town' initiative for England in 2009, with initial plans for 12 sites eventually reduced to four (North-West Bicester, Rackheath, St Austell, and Whitehill-Bordon). Meanwhile, several individual UK cities such as Aberdeen, Coventry, Manchester, and St Davids embarked on eco-city initiatives of various kinds.

In North America, the cities of Portland, Vancouver, and Toronto launched, respectively, the 'EcoDistricts' (2009), 'Eco-Density' (2008) and 'Greenest City' (2010), and 'Living Green

Figure 1 Number of eco-city initiatives launched by each date – globally and by regions. Source: Joss, S., Tomozeiu, D., Cowley, R., 2011. Eco-cities: A Global Survey 2011 (Eco-city Profiles), University of Westminster, London. http://www.westminster.ac.uk/ecocities (accessed November 2012).

Box 1 Tianjin eco-city (China) – sustainable urbanism through urban expansion

A flagship initiative launched in 2008 with support from the Chinese government and developed through bilateral cooperation with Singapore, Tianjin Eco-City is a new, large-scale urban development near the historic city of Tianjin in northeast China. Covering an area of approximately 30 km^2 nonarable land, the city will be home to 350 000 residents upon completion, which is expected in 2020. The city layout follows an integrated mixed-land use pattern: 400 × 400 m 'eco-cells' form the core design unit; every four to five eco-cells combine to form differently landscaped 'eco-neighborhoods' of approximately 20 000 residents; and 'eco-valley' corridors link the eco-neighborhoods and serve as main public open spaces stretching across the city. Ninety percent of transportation is to be by public transport (light-rail, bus, and trams), cycling, and walking. At least 15% of energy consumed should be from renewable sources, including geothermal and solar energy. Waste management will focus on reducing and recycling waste, with energy from waste incineration supplying the district energy system. At least half of the water consumed is to come from desalination and water-recycling processes. The existing wetlands around the city will be protected to enhance biodiversity. Twenty percent of housing is to be 'affordable', enabled through public housing subsidies.

Official website: http://www.tianjinecocity.gov.sg/

Toronto' (2010) initiatives, thus building on their earlier international reputation as innovators in urban sustainability (see Box 2 for more on Portland's EcoDistricts). Elsewhere, a dozen or so new infill and retrofit eco-city initiatives were launched, including 'Eco-city Alexandria' (Alexandria, Virginia, USA), the 'Seattle 2030 District' (Seattle, Washington, USA), and 'Dockside Green' (Victoria, British Columbia, Canada). Across Latin America, among the significant new eco-districts launched in the mid-2000s are 'Panama Pacifico,' a new district of Panama City (Panama) that styles itself as 'Latin America's first green city,' and 'Pedra Branca,' a new compact district of Palhoça (Brazil). In Africa and the Middle East, there have been fewer initiatives to date, although the unprecedented rate of urbanization and associated environmental pressures across much of Africa suggest a possible surge of eco-city developments in this global region in years to come. Among the initiatives launched in the 2000s, Masdar (UAE) has generated by far the most media interest globally. Other notable initiatives include 'Hacienda Ecocities' in Mombasa (Kenya); 'Eko Atlantic City' in Lagos (Nigeria); 'Ivory Park Eco-City' in Johannesburg, 'Menlyn Maine' in Pretoria, and 'Zonk'izizwe Town Center' in Johannesburg (all South Africa); and 'Sseesamirembe' in Kampala (Uganda).

Ubiquitous Eco-city

Apart from these numerous national developments, several international initiatives were launched in the 2000s. Their function variably entails providing support (conceptual, practical, and financial) for local initiatives, encouraging international knowledge and policy transfer, and acting as certification and endorsement schemes. Among these initiatives, the World Bank's Eco^2 Cities ('ecological cities as economic cities') initiative has, since its launch in 2009, been active mainly across Asia, including China, Indonesia, the Philippines, and Vietnam. The Organization for Economic Cooperation and Development (OECD)'s Green Cities program has engaged in comparative analysis and conceptual development relating to metropolitan regions in several of its member states, including France, Japan, Korea, Sweden, and the United States. Notable international nongovernmental initiatives include the Climate Positive Development Program ('Climate +'), which was launched in 2009 by the Clinton Climate Initiative with the participation of 17 cities and which in 2011 merged with the C40 Large Cities Climate Leadership Group ('C40'), thus bringing together over 70 cities in a global network; One Planet Communities, an initiative coordinated by BioRegional, a UK-based social enterprise, which includes five projects in Portugal, the United Kingdom, and the United States in its endorsement scheme and is involved in a further 11 projects around the world; and the International Ecocity Framework and Standards, a methodological framework and certification tool launched in 2010 by US-based Ecocity Builders.

Another feature of the internationalization of eco-city developments is the increasing prominence of global architecture, engineering, planning, and technology consultancies. European-based firms, such as Arup (UK), MVRDV (the Netherlands), and SBA Design (Germany), have become involved in master-planning, design, and development capacity in numerous initiatives, mainly in Asia. Similarly, technology firms have begun to take a close interest in the development of various 'smart technology' solutions in support of sustainable urbanism. For example, Hitachi of Japan is involved in the development of the four 'eco-friendly' cities

Box 2 Eco-districts, Portland (USA) – eco-innovation at the neighborhood level

Ranked regularly as one of the 'greenest' US cities, Portland, Oregon, has a legacy of innovation in urban sustainability dating back to the 1980s. More recently, in 2009, the city established the Portland Sustainability Institute, as part of which it launched the EcoDistricts initiative, on the basis that the neighborhood level is particularly effective for implementing sustainable urban development. In the pilot phase, the initiative is developed across five different districts in partnership with local organizations and community groups. Each EcoDistricts initiative is characterized by place-specific aspects. For example, the South-of-Market (SoMa) Eco-District involves Portland State University together with over a dozen other major property owners in the area; the aim is to improve the district through green streets and public transit and, thus, become an attractive place for business to locate. The university contributes to this through its substantial sustainability research base. Another example is the Foster Green Eco-District encompassing a cluster of suburban neighborhoods in the southeastern part of the city. Here, the focus is on enhancing the quality of life and addressing community needs and priorities, by improving economic vitality, public safety, public transportation, as well as access to open space. Beyond Portland itself, the EcoDistricts initiative has been developed into a network of US cities, including Boston, San Francisco, Seattle, and Washington, DC.

Official website: http://ecodistricts.org/

planned for the 'Delhi–Mumbai corridor,' with focus on integrated public transport systems, recycling technology, and 'smart grid' digital technology. In the United Kingdom, technology firms IBM and Toshiba have joined a consortium of private and public organizations to deliver similar smart grid solutions (integrating wind, tidal, geothermal, and solar energy generation) in connection with the 'Eco Island' initiative launched by the Isle of Wight (UK) in 2011.

The developments across these three periods suggest a gradual shift toward what may be called the 'ubiquitous eco-city' (Joss et al., 2013). This shift is characterized by accelerated practical innovation and implementation spread across various global regions, and the involvement of new actors through various forms of public–private partnerships. It occurred as a result of broad policy developments: initially against the backdrop of the growing environmental movement, the eco-city was conceptualized 'bottom-up' by activists, practitioners, and academics in response to local urban problems – such as urban sprawl, inner-city deprivation, and environmental pollution – and as an alternative to mainstream urban planning. With the adoption of sustainability as governmental policy, eco-city concepts became increasingly defined as part of policy and regulatory discourses, mainly at local and national levels. In the post-Kyoto era, the twin factors of global climate change and rapid urbanization prompted a dominant, international policy response in the form of the 'environmental modernization' agenda. (The UN Framework Convention on Climate Change – the 'Kyoto Protocol' – came into force in 2005; and in 2008, for the first time in human history, the majority of people now live in urban areas; UN Habitat, 2008.)

This, in turn, has resulted in an increasingly internationalist interest in practical eco-city innovation, at the heart of which is seen the opportunity to marry economic development with environmental sustainability. The World Bank's *Eco^2 Cities* program and the OECD's Green Cities program are illustrative of this more recent global conceptual direction. This is also mirrored at the national level through the recent launch of governmental programs – such as those by China, France, India, Japan, and South Korea – in support of green growth and urban sustainability policies in general, and various eco-city initiatives in particular, that together significantly account for the surge in eco-city projects. In comparison with earlier periods, the contemporary 'ubiquitous' eco-city is much more likely to be developed with a strong focus on promoting 'green growth' through international knowledge transfer activities – and particularly involving international private firms; it is more explicitly defined by a central 'carbon' agenda and more overtly driven by related 'green-smart' technological innovation. Finally, the shift toward the 'ubiquitous eco-city' has been characterized by growing efforts to define sustainable urbanism through international frameworks and standard schemes.

Challenges

The development of eco-cities – as both a concept and practice of sustainable urbanism – has been shown to be complex; as a consequence, it faces several interrelated challenges. Among these, four stand out in particular: first, some critics argue that, by their very nature, cities are inherently unsustainable judging by their ecological footprints (see, e.g., Rees and Wackernagel, 1996; Rees, 2010). Even cities considered to be at the forefront of sustainability efforts have been found to have ecological footprints several dozen times larger than their actual area. This applies to existing cities as much as to new urban developments. In the case of the latter, problematically the (often significant) construction-related environmental impacts, such as GHG emissions, are sometimes excluded from the eco-city profiles presented. In response, proponents would argue that eco-city initiatives, as part of an ongoing transition process, at least move toward more sustainable urban development in comparison to the status quo, with reference to concrete examples of improvements in relation to measures such as carbon emissions, water pollution, public transport, and 'livability'. This debate points to the need to scrutinize critically various 'eco-city' claims made and to develop more stringent indicators and standards to define and assess urban sustainability. As such, it lays bare the fact that in many cases, beyond statements of intent and future projections, systematic, independently verified evidence of actual eco-city achievements is currently hard to come by. This debate also points to the need to consider the city in relation to its wider hinterland, as arguably urban sustainability can be meaningfully discussed only from a broader bioregional perspective.

The second challenge, from an urban policy and planning perspective, is the charge that many eco-city initiatives represent premium 'ecological enclaves' (e.g., Hodson and Marvin, 2010). According to this perspective, the eco-city creates and reinforces premium developments aimed at providing more secure and higher standard urban living environments for a more affluent clientele. As such, it can be seen as part of a wider neoliberal trend toward achieving urban-ecological security. 'Hacienda Ecocities' in Kenya is an example of an initiative promoted as offering price stability, service reliability, and security for its mainly middle-class residents (Joss et al., 2011: 54–55). In a similar vein, some of the plans and designs for new eco-cities in China demonstrate an aspiration for Western-style, high-end urban developments that stand in contrast to existing mainstream urban living there (Joss and Molella, 2013). The increasing involvement in recent years of international consultancy firms in the financing, master planning, and delivery of eco-city initiatives further underlines the trend toward sustainable urbanism as an investment and development opportunity. The challenge here is that the eco-city may fail to provide a solution to urban sustainability that is accessible to wider communities and addresses environmental, economic, and social sustainability issues beyond the 'premium enclave' itself. However, from an innovation perspective, it can be argued that the initial 'niche' development over time can be expected to become mainstream, thus benefitting cities more widely. Furthermore, the 'ecological enclave' discourse is only one among several (contrasting) discourses shaping contemporary eco-city initiatives. 'Ivory Park EcoCity' (Johannesburg, South Africa) is an example of an initiative emphasizing community-based sustainability innovations supporting indigenous practices

and local enterprise (Joss et al., 2011: 63). Portland's EcoDistricts initiative promotes sustainable neighborhood development through the active involvement of five communities across the city (Joss et al., 2011: 82).

A third challenge arises from the increasingly central role placed on technology to provide solutions for eco-city development. On the surface, this is about the application of an array of green technologies. However, emerging cities, such as 'Tangshan Caofeidian International Eco-City' – also referred to as China's first 'information eco-city' – appear to conceive of the eco-city more generally as high-tech cities (Joss and Molella, 2013). This manifests itself in the integral use of 'smart' technology for digitally linking up and coordinating various urban systems in an overarching information system. The Japanese technology firm Panasonic is involved in developing 'Fujisawa Sustainable Smart Town,' designed as a high-tech city with advanced solar power generation, heat pump, and hot-water systems connected by a 'smart grid' that allows for city-wide, real-time systems management. In Portugal, 'PlanIT Valley' is designed as a high-tech district of Paredes, based on the concept of a replicable 'urban operating system' (Joss et al., 2013). Such heavy emphasis on technological innovation and solutions runs the risk of conceptualizing the eco-city narrowly as physical infrastructure and an urban technological system. Instead, insights from science and technology studies (STS) point to the need to consider the function of technology more broadly in terms of socio-technical relationships (human–technology interaction). Furthermore, from an urban politics perspective, the application of technology should be considered in terms of its place-making quality – that is, how it can enhance community and citizen engagement, support political discourse, and create livable urban space.

This points to the fourth challenge, relating to governance (Joss, 2011b; Rydin, 2010). Given the complexity of sustainable urbanism, which typically cuts across organizational, policy sectoral, geographical, and jurisdictional boundaries and involves a multitude of actors (local, national, international, public, and private) in various configurations, the issue of governance comes to the fore. Steering, negotiation, coordination, and integration are all essential parts of the planning, development, and implementation processes of eco-city initiatives. The nature and mode of governance vary depending on, among other factors, the type and scale of initiative (retrofit, infill, and new) and the wider policy and political contexts. The challenge consists of putting in place governance arrangements that are sufficiently effective, efficient, and robust to allow the implementation of eco-city development plans across often lengthy time periods (two or more decades are not untypical) and involving considerable financial and organizational resources and risks. It further consists of adopting governance modes that enable urban sustainability innovation processes, through which new ideas, designs, and practices can emerge. Finally, it consists of enabling political and public accountability, by rendering decision-making structures and processes (such as public–private partnerships) transparent and open to scrutiny, and by promoting meaningful stakeholder and community engagement.

Conclusion

Sustainable urbanism and the eco-city owe much of their current popularity to the forceful combination of global climate change concerns and a rapidly urbanizing world population. The translation of concepts into practice through various types of eco-city initiatives has been enabled by a broad coalition of involved actors, with municipal authorities, national governments, private firms, and international organizations all instrumental in driving innovation. This mainstreaming has resulted in several ubiquitous tendencies, characterized by underlying 'green growth' strategies, a dominant 'carbon discourse,' the preponderance of 'smart' technological solutions, and increased policy and knowledge transfer activity spearheaded by internationally active consultancies and governmental and nongovernmental organizations dedicated to promoting urban sustainability. Efforts to arrive at national and international frameworks and standards for the sustainable city have added to this ongoing consolidation process. Counteracting these ubiquitous tendencies are local settings and contexts through which sustainable urbanism is implemented. As a result, certain tensions are built into eco-city development, requiring the reconciliation of international concerns (e.g., the reduction of GHG emissions) with local priorities (e.g., promoting economic development and addressing place-specific environmental problems and social needs). Governance is an essential requirement of sustainable urbanism, to enable the effective coordination and integration of the intrinsically complex, multifaceted structures and processes involved. Faced with the rapid growth of practical initiatives on the ground as part of an ongoing period of innovation, there is a present need for critical, multidisciplinary analysis of proposed concepts and projects, as well as the substantive evaluation of achievements to date. In turn, this will help bring about the transition to the next generation of eco-cities.

Ecocultural Theories of Development

A Bame Nsamenang, University of Bamenda, Bamenda, Cameroon

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article conceptualizes human-lived contexts and their cultures not as variables but as developmental provocateurs. This view is proposed because environments are inhabited spaces, that serve as settings that shape human development. Although culture is both inside and outside the individual, the 'culture' that channels developmental outcomes is inside the individuating self as a core facet of the ecocultural paradigm. Analysis of variants of ecocultural theories reveals diversity in mindsets regarding the role of physical and cultural contexts in development. The developmental impact of these roles has been mainly unexplored. A critique of efforts to evolve a unified developmental science shows that existing approaches are mostly skewed toward Euro-Western views and reveals a neglect of varied social constructions of childhood and conditions of children from across the globe.

Introduction

This article proposes a novel approach to conceptualizing the role of lived ecological contexts and their cultures in human development research as developmental provocateurs, rather than simply considering them as variables. This approach recognizes the primacy of the context in general and the lived or developmental context in particular for every human being, thereby departing from the earlier conceptualization and theorization of human development as if it were a decontextualized, culture-free phenomenon. A physical place and its ecological, social realities and cultural contents should be at the forefront of developmental research thinking. In short, the ecocultural approach considers human development to take place in a context that includes both environmental and cultural influences (which serve as both constraints and facilitators).

Although culture is both inside and outside the individual, the frame of reference from a developmental position is that "culture [is] inside the person" (Poortinga, 2011). The article adopts and innovates from the heuristic seminal ecocultural paradigm of John Berry (1966, 1971, 2011), incorporating subsequent versions of ecological thinking, particularly the integrative approach of Pierre Dasen (2003), in efforts to point to the global diversity of developmental contexts in their physical and cultural dimensions. This article examines variants of ecocultural theories of human development, and the effort to evolve a unified developmental science that reflects global human diversity.

Cultural Ecology

The concept of cultural ecology refers to the changing relationships between culture and the environment (Bada, 1995; Everette, 1996) or the total web of life (Steward, 1955), through developmental adaptations (Berry, 1976; Cohen, 2001). How cultures interact with the environment is related to how societies confront and solve the common problems of human existence (Thomas, 2008). Culture, thus, gives meanings to one's way of life and provides the possibility of control over the environment. Cultural constructions, such as norms, values, and myths, in turn, allow people to make sense of the environment (McCarthy, 1998). The undeniable interdependency between ecology and culture is crucial for the understanding of human development in general and of human relations in particular. Thus, cultural ecology can be said to be one of the key ingredients of future human development studies.

Generally, cultures in different parts of the world are often linked to the given availability of natural resources, climate, terrain, and geographic latitude (Hofstede, 2001; Triandis and Suh, 2002), although structural barriers could reduce or eliminate access to them. Each culture has developed its own unique structure for dealing effectively with its environment, given its available resources (Trompenaars and Hampden-Turner, 1977).

Berry (1966) noted that culture contact induces culture change through the process of acculturation. Nsamenang (2011) described cultural and psychological change resulting from the intermingling of cultural traditions through increasing waves of immigration and settlement in 'other' people's cultural areas. Fang (2009) noted that these external changes often result from cultural clashes and collisions, with cultural mixing processes usually being demanding and exciting (Remer, 2005). Cohen (2001) has described how cultural value adaptation of a people was influenced by their correct or mistaken given beliefs about what others will do, which eventually leads to the value equilibrium both on domestic and world levels. The distinction between hunter-gatherer and agricultural societies, for example, is a clear indication of the cultural ecology causality that developmental research ought to pursue.

Developmental science research should be adopting a dynamism-oriented ecocultural model because developmental processes and cultural conditions of human development and livelihoods are dynamic, changing, and sometimes overtly illogical and incoherent. Cultural ecology can elucidate the dynamic, changing nature of culture (Bird and Fang, 2009; Chou, 2009).

Ecocultural Theorization: Conceptual and Theoretic Thrust

The term *ecocultural* is a hybrid, coined from two concepts, ecology (referring to a physical place and its ecosystem that includes networks of people and children) and culture. The concept is rooted in the view that human development is influenced by both the ecological context, and the cultural context, whose features are often adapted to the ecological setting (Berry, 1966, 1971, 1976). The ecocultural approach has a long history (Jahoda, 1995) and many variants. In this approach, culture consists of concrete aspects (such as tools) as well more subjective features (such as belief systems, oral traditions, literacy, and language) and the different ways of thinking and acting about various aspects of life. The ecocultural framework situates the developing human being not in a universal culture but within a culture that is context bounded by a geographical or physical environment and characterized by a social system that includes the cultural imperatives of the people who inhabit or are active in that ecosystem.

The ecocultural model of human development is a Eurocentric enterprise (Nsamenang, 2002) in that theoretical and empirical efforts have focused overwhelmingly on the ecological and cultural realities of the Minority (Western) World to the relative neglect of those of the Majority World where the bulk of humanity, especially those of the world's child and youth cohorts, reside. In the Western worldview, maturity is portrayed in terms of increasing autonomy from parents and where identity development is described as a process of exploration among relatively unrestricted educational and career opportunities (Adams et al., 1992). Such accounts omit the dreadful experiences of ethnic minority youth, as well as those of Majority World children and youth, who often have early and lifelong responsibilities to family members and who face structural barriers to opportunities in school and work (Grotevant and Cooper, 1998). Furthermore, McLloyd (1991) has shown how race-comparative designs create norms based on European American, middle-class experiences. These norms lead readers to interpret differences between ethnic groups and Majority World children and youth as deficits from the mainstream and to view non-Western children, youth, and their families in terms of negative stereotypes.

Laypersons as well as research scholars often think of or handle ethnicity, culture, and family as broad categorical qualities that are relatively uniform in each group and static or stable across time and context. For example, European Americans are often labeled individualistic, whereas African-Americans, Asian-Americans, Latin-Americans, and Native Americans, and Majority World peoples in general, tend to be portrayed as collectivistic or interdependent in outlook and lifestyle. Oversimplified categories such as ethnicity, culture, and family, were questioned by anthropologist Beatrice Whiting (1976) who challenged scholars to begin 'unpackaging' these categories to understand their multiple dimensions and components. In the same vein, Weisner et al. (1988) argued

> culture is not a nominal variable to be attached equally to every child, in the same way that age, height, or sex might be. Treating culture in this way assumes that all children in a cultural group have common natal experiences. In many cases, they do not. The assumption of homogeneity of experience of children within cultures, without empirical evidence, is unwarranted…. A similar error is to treat national or ethnic status as equivalent to a common cultural experience for individuals (p. 328).

Most extant human development theories tend to be presented as universally applicable; however they are culture-infused and only a few inform how context and culture shape biological development. So, researchers need to figure out how to move beyond the categorical treatment of ethnicity, culture, and family to their dynamic merging in individuals.

The Original Ecocultural Theory: Berry

John Berry's (1966) ecocultural approach represents an attempt to resolve the tension between culture as an entity in its own right and the playing out of adaptation in the individuals and collectivities that nurse on this maternal resource as they attempt to know, integrate, and perform in their cultural context and beyond it in the face of acculturative pressures. Berry (1966, 1971, 1976) was convinced that human beings develop in ways that permit their adaptation to and long-term survival in, particular, ecosystems.

Ferguson (1956) laid the foundation for the ecocultural approach by articulating what was later called (by Irvine and Berry, 1988: p. 121) the "Law of Cultural Differentiation" of human abilities: "Cultural factors prescribe what shall be learned and at what age; consequently different cultural environments lead to the development of different patterns of ability." These "different patterns of ability" were construed by Berry (1976) as "cognitive styles," particularly that of "field dependence and field independence." Variations in the development of these styles were then linked to the ecological and cultural contexts in which individuals develop. These contexts were understood within the anthropological school of 'ecological anthropology.'

Figure 1 presents the ecocultural framework. A main feature of this framework is to distinguish the population and the individual levels of analysis of developmental influences and outcomes. It views cultures as evolving adaptations to ecological and sociopolitical influences, and views individual psychological characteristics in a population as adaptive to their cultural contexts.

There are five main features of the ecocultural model: *ecological context; sociopolitical context; population adaptations* (both cultural and biological*); transmission variables* that serve as vehicles for population characteristics becoming part of the behavior of the individual; and *behavioral outcomes*.

In addition to populations adapting to their ecological and sociopolitical contexts (on the left of **Figure 1**), a key component of the ecocultural framework for understanding development is the set of transmission variables (in the middle) between these contexts and adaptations, and individual psychological development (on the right side). In essence, we need to examine the various ways in which cultural features of populations to varying degrees become incorporated into the repertoire of individuals. Four such variables are

Figure 1 Ecocultural framework linking ecology, cultural adaptation, and individual behavior. Berry, J.W., 2003. Ecological perspective on human psychological development. In: Saraswathi, T.S. (Ed.), Cross-cultural Perspectives in Human Development: Theory, Research and Applications. Sage, New Delhi, India, p. 55.

identified: direct ecological influences (without any explicit social or cultural mediation), genetic transmission from parents to offspring, intergenerational transmission of cultural characteristics (through the processes of socialization and enculturation), and acculturation (through sociopolitical influences impacting from outside the culture).

Dasen (2003) perceives the ecocultural framework as very broad, and although cultural transmission figures as a central process, the framework is not specifically designed to deal with human development. The next section reviews the ecological systems theory (EST) of Bronfenbrenner (1979) that takes the developing person as a focal point.

The EST: Bronfenbrenner

The EST positions human development within systems of superimposed 'layers' of environmental settings, each impacting differently on human development. The initial and most utilized version is Bronfenbrenner's (1979) EST that identifies developmental influences at four levels: macro-, exo-, meso-, and microsystem, which correspond to intercultural, community, organizational, and interpersonal or individual levels. Prior to Bronfenbrenner's (1979) framework, many research theorists had traditionally considered only a dichotomy of perspectives, either micro (individual behavior) or macro (effect of cultural factors). The EST was focused on the person, the environment, and the continuous interaction of the two. This interaction constantly evolves and develops both components. However, it is not only the environment that directly affects the person, but there are layers in between, which all have resulting impacts on the next level. The individual, organization, community, and culture are nested into each other, like Russian dolls, with each level operating fully within the next larger sphere.

The EST theory holds that development reflects the influence of five ecological subsystems:

Microsystem

The setting in which the individual lives or undertakes routine activities. This includes the child's family, peers, school, and neighborhood. It is in the microsystem that the most direct interactions with social agents take place; with parents, peers, and teachers, for example. The child is not a passive recipient of experiences in these interactions, but someone who contributes to construct the nature of the settings. A child's own biology is considered part of her or his microsystem.

Mesosystem

Refers to relations between microsystems or connections with the other contexts, such as the relation of family experiences to school experiences, school experiences to church experiences, and family experiences to peer experiences.

Exosystem

Involves links between a social setting in which the individual does not have an active role and the individual's immediate context. For example, a husband's or child's experience at home may be influenced by a mother's experiences at work.

Macrosystem

Describes the culture in which individuals live. Elements of macrosystms include the cultural contexts of developing and industrialized countries as well as their socioeconomic status, poverty, and ethnicity, among many others.

Chronosystem

Refers to the structure of environmental events and transitions over the life course, as well as across social-historical circumstances. For example, divorce is one transition and family relocation or migration for whatever reason is another.

Each of the five systems is characterized by roles, norms (expected acceptable behavior), and relationships or social networks, including those of children. For example, children tend to act differently within their own family than within a classroom and toddlers can be observed to act differently in peer cultures than in the presence of adults.

The Developmental Niche Framework: Super and Harkness

The *developmental niche* (Super and Harkness, 1986) is a theoretical framework for understanding and analyzing how culture shapes child development. It is an ecologically grounded theory that, like Weisner's (2002) "ecocultural niche," Worthman's (1994) "developmental microniche," and Nsamenang's (1992) social ontogenesis, has the same origins as EST. Developmental niche theory is a variant of the ecocultural model that integrates two basic principles from cultural anthropology and developmental psychology. First, that a child's environment is organized as part of the cultural meaning system of a cultural community. Second, that a child's biological disposition, including attributes, temperament, skills, and potentials, affect her or his process of development. The two overarching principles of the developmental niche framework are: a child's environment is organized in a nonarbitrary manner as part of a cultural system; and the child's own disposition, including a particular constellation of attributes, temperament, skills, and potentials, affect the process of development. The developmental niche is seen as the composite of three interacting subsystems:

physical and social settings: who is there, what affordances are provided by the physical space and social others;
customs and practices of child rearing: what are the inherited and adapted ways of nurturing, entertaining, educating, and protecting the child; and
the psychology of the caregivers: particularly parental ethnotheories of child development and parenting, which play a directive role in actual childcare practices.

The three subsystems of the developmental niche (settings, customs, and caregiver psychology) share the common function of mediating the child's developmental experiences within the larger culture. The three components of the developmental niche operate together with powerful though incomplete coordination as a system. Thus for example,in a stable cultural environment, customs of care reflect parental ethnotheories about the child, and they are further supported by the physical and social settings of daily life. In circumstances of rapid social change, or immigration, there will be greater inconsistency among the subsystems, but one can usually discern homeostatic processes or acculturative forces at work in the context of changing beliefs and practices and their consequences on children.

Each of the three subsystems of the niche is functionally embedded in other aspects of the human ecology in specific and unique ways; in other words, the three subsystems act as the primary channels through which the niche, as an open system, is influenced by outside forces. Any one of the three components may be a primary route of influence. For example, economic or social change may lead to new settings for children. Moreover, each of the three subsystems of the niche is involved in a process of mutual adaptation with the individual child. Thus, the age, gender, temperament, energy level, and talents of the individual child influence parents and others in the niche and modulate cultural expectations and opportunities for the child at any given time. The developmental niche framework makes evident the kind of systematic regularity that culture provides – environmental organization that emphasizes repeatedly or with singular salience the culture's core 'messages.' This quality, called 'contemporary redundancy,' is important for the acquisition of skills and values as it offers multiple opportunities for learning the same thing, whether that 'thing' is reading, caring for others, the communication of emotions, or the value of 'independence.'

Social Ontogenesis: Nsamenang

Nsamenang (1992) developed a theoretical position termed *social ontogenesis*, based on an indigenous West African conception that is phrased within an ecocultural perspective. His ideas are inspired by the writings of various Africans trained in philosophy and the humanities (e.g., Mbiti, 1990; Moumouni, 1968) and grounded in a combination of systematic observational research and his own personal experience of the socialization practices of the rural versus urban Nso communities in Western Cameroon (Nsamenang and Lamb, 1993, 1995). His formulation of social ontogenesis is rooted in a widely shared West African worldview. It posits the growth of social selfhood through a series of phases, each characterized by a distinctive developmental task, defined within the framework of the culture's primarily socioaffective, developmental agenda. The theory of social ontogenesis (Nsamenang, 1992, 2004, 2012a) points out how, beginning early in life and through developmental stages, African children are active in the life of their families and societies as well as in self-care and self-learning. This theory presents human development as partly determined by the social ecology in which the development occurs and by how African children, especially in sibling and peer settings, learn from each other in peer cultures.

The seminal concept of this theory is sociogenesis, defined as individual development that is explained more in terms of socially observed markers and culturally perceived tasks but less on biological unfolding, although social ontogenetic thinking does not preclude nature; it assumes that biology underpins social ontogenesis (Nsamenang, 2006a). Ngaujah (2003) has interpreted Nsamenang's theoretical approach as revealing the social and affective nature of the environment on the child's cognitive and social learning.

The first phase of social ontogenesis is the *ceremony of naming*, which projects the kind of socialized being the neonate should become. The major developmental task of the second phase is success in *social priming*: babies are cuddled and teased to smile along with adults; parents and other caregivers offer infants food items and playthings, and lure them both verbally and through nonverbal communication to return the 'gifts.'

This is a preliminary step toward induction into the 'sharing and exchange norms' that bond siblings and the entire social system together. For example, among the Chewa and Tumbuka peoples in Zambia, Mtonga (2012) interprets such interactions of adults with toddlers, as aimed at cultivating generosity and preventing the development of greediness or selfishness.

The next phase, roughly corresponding with childhood, is termed the period of *social apprenticing* in which the principal developmental task is to recognize, cognize, and rehearse social roles that pertain to three hierarchical spheres of life: household, network, and public. Much of the responsibility for stimulation and guidance in this phase of early childhood development is assigned to preadolescent and adolescent children in the family and the neighborhood. The delegation of responsibility for care and socialization of younger children from adults to preadolescents and adolescents serves the function of *priming* the emergence of social responsibility. These priming strategies embedded in traditional African child-rearing practices have important implications for the design of culturally appropriate forms of intervention to optimize developmental opportunities for children in contemporary Africa (Nsamenang, 2009). Indeed, in many African communities with a subsistence economy, far from constituting a form of exploitation or abuse, caregiving responsibilities assigned to preadolescents and adolescents are better understood as part of "an indigenous educational strategy that keeps children in contact with existential realities and the activities of daily life [that] represents the participatory component of social integration" (Nsamenang, 1992: p. 157).

By positioning children as emerging into levels of selfhood, implying the unfolding of biological potentialities and social competencies, Africans tacitly acknowledge that self-concept and agency evolve with a maturing self-consciousness that accords a sense of self-direction and agentive search for or choice of the resources and exposures that increasingly differentiate and polish self-identity and goal-directed behavior toward desired or imagined personal status, either of sovereign individuality or relational individuality (Kagitcibasi, 2007; Nsamenang, 2004).

African parents sensitize children from an early age to seek out others from whom to extract local knowledge and situated intelligences (Ogbu, 1992) and in so doing clarify who they are, more so within sibling and peer spaces than with adults. Children extort the social, emotional, practical, cognitive, relational values and other norms ingrained in the activity settings of the home, society, and peer cultures more through their contextual embedment and active participation and less through explicit adult instruction or prodding. In so doing, they 'graduate' from one activity setting and participative sector of the peer culture to another, steadily maturing toward adult identity and roles (Nsamenang, 2012a). Zimba (2002: p. 94) described one instance of self-definition with the Zulu community of South Africa, as nurturing *umuntu umuntu ngabantu*, which literally translates into "a person is only a person with other people." This relational view of identity development downplays lonesome individuation, implying that a sense of self cannot be attained or adequately understood without reference to the 'community' of others in which it is embedded. Concepts of place identity and place attachment accentuate the need to incorporate context into theory building and research agendas.

Applications of the Ecocultural Approach

Applications of these ideas are helpful when creating settings for development. We may begin by recognizing the universal needs of children. Children's essential needs include warm, caring, and responsive adults; a sense of importance and significance; a way to connect, belong, and relate to the world around them; opportunities to explore and play; and people to help structure, guide, and support their learning and opportunities for self-esteem and self-actualization. A basic human need is the need to belong. Children need to feel they belong, too. They need to be close to people they know; have familiar, safe, and comfortable play objects; and be in a setting that has a personal history for them. Young children need to feel important. Children need to feel that what they do is meaningful to someone other than themselves, particularly adults. In the distant past, these needs were met at home and in the community, but today, for the majority of children and young people worldwide, they are being met in centers, classrooms, or other group engagements, wherein new challenges, even abuses, are emerging in some of them. Children need to explore, experiment, and learn basic knowledge and skills through direct experience.

In spite of the enormous variation across cultures in the perception of childhood and children's needs and childcare arrangements to satisfy them, the Convention on the Rights of Children (UNICEF, 2003) recognizes the family as the most appropriate societal institution to best serve the interests and needs of children. But family types, their composition, and role vary by culture, social class, and ecocultural circumstances (Nsamenang, 2012b).

So, in early childhood care and education (ECCE) centers and schools, we can capitalize on the African family practice of children being accredited skilled partners in peers and siblings' zones of proximal development to redesign curricular content, learning spaces, and pedagogic approaches.

Childhood is a time when children should learn firsthand about the physical world: the feel of water, dust, or mud, the constant pull of gravity, the stench of rotten fruit, and the abrasive feel of sand or concrete on a bare knee. Play provides a way for children to integrate all their new experiences into their rapidly developing minds, bodies, emotions, and social skills. Brain research supports this idea, stressing that children learn best through an integrated approach combining physical, emotional, cognitive, and social growth. Education in African family traditions is part and parcel of cultural life. It is integrated into the daily routines of the family and community and does not compartmentalize knowledge into say, agriculture, economics, arts, sciences, etc. Instead, it integrates knowledge about all aspects of life into a single curriculum. The curriculum is arranged in sequence to fit into different milestones of development that the culture perceives or recognizes (Nsamenang, 2006b: p. 329–330). The role of the parent, mentor, including the peer-teacher, teacher is critical in a child's life. Children depend on knowledgeable others to be their confidant, colleague, model, instructor, and nurturer of learning experiences. Clearly children need lots of exposure

to other people in their early childhood years as well as to a wide variety of learning and play settings.

An early childhood environment is many things: it should be a safe place where children are protected from the elements and are easily supervised, and it is where the routine daily activities take place, such as playing, eating, sleeping, washing hands, going to the bathroom, etc. The ecocultural theory holds that a universal task for all families is to organize a sustainable daily routine (Weisner, 1984). The theory assumes that family adaptation involves balancing ecology (resources, constraints), culture (beliefs, values, and schemata), and the needs and abilities of family members in the organization of daily routines (Gallimore et al., 1989). A family's daily routine is dynamic and changes according to its needs. How it addresses these needs is filtered by perceptions and concrete use of resources and constraints, with the actual resources and constraints of the environment. This often involves negotiating options and balancing competing demands. For example, household management involves attending to domestic chores like food preparing and domestic chores as well as supervising children's development and school work. A village mother may decide to forego a farming task in order to take an ill child to hospital. In this example, the family ecology characterized by limited time, no assistance from the husband, and sociocultural values such as a child's health and learning are linked to changes in the family's routine.

Each community that children belong to makes its own specific curriculum demands: the community of learners who will be able to respond to challenge and change; the community of children who have individual needs and rights; and the community of Africans, for example, who are gaining knowledge of their nation's languages and are developing skills in using cultural tools such as art, dance, mathematics, music, reading, science, technology, and writing. The learner and her or his immediate locale, for instance, different activity settings, are at the center and the first level for learning. Other levels have a powerful influence on the child's well-being and capacity to learn. The second level contains the major settings experienced directly or vicariously by the learner: the child's own home, the service or setting beyond their home through mass media and cyberspace, for example, and the relationships between these settings. A third level that influences the quality of children's experiences, encompasses the world of work, the neighborhood, the mass media, and cyberspace if the child is exposed to it, as well as informal social networks. It also includes the conditions that influence the well-being and support of the adults in the children's lives: the demands, the stresses, and the opportunities for development experienced by significant adults in each child's life. The national level is the most encompassing, including the nation's philosophy about the value of early childhood care and education and about the rights and responsibilities of children. Although ECCE is mainly concerned with the lower levels, these highest levels are important influences on the quality of the curriculum.

Conclusion

The ecocultural perspective informs us that the young of every species have basic needs that must be met for them to survive, thrive, mature, and develop, expectedly into adult members of the society. It also informs us that across the globe, people of every culture and ecology fulfill these tasks in divergent ways. All cultures worldwide are constantly engaged in a constant search for ways of understanding and building on the developmental contexts to maximize human potential. In fact, human biology is wired to acquire, create, and transmit culture. As biology interfaces with culture, it is not just a preface to or foundation for human development but a consistent theme throughout its process (Keller, 2007). The human brain, for instance, is built to be modified by the environment and culture in which it develops. Thus the nervous system is culturally interactive and a bearer of cultural difference, or, put more comprehensively, "Culture…is a determinative complement of genotype that shapes human psychosocial differentiation in the direction of a given people's cultural meaning systems" (Nsamenang, 2008b: p. 73). Given that cultures infuse their own agendas onto a natural, biological program of human ontogenesis (Nsamenang, 1992), the notion of adaptation to varied environments should be carefully considered and systematically worked into developmental research agendas.

Social ecology is the study of people in an environment and the influences they exert on their environment and on one another, including children on themselves and their interlocutors. The interaction between factors in children's maturing biology, their immediate family/community environment, and the societal landscape fuels and channels development (see Nsamenang and Akum, 2013). Thus, interactions with others and the environment are central to human developmental outcomes. As such, contextual interactionism constitutes a theoretical framework or mind-set for analyzing various types of context in which children live and how they are cared for and educated in their early years. This model allows for the integration of multiple levels of interaction with contexts and its people and opportunities or constraints to establish the big picture of forces that influence child development.

Abstract

This article summarizes the history of ecofeminism and its various strands of activism and intellectual inquiry. Through critiques made of ecofeminism, both from those allying themselves with the movement, and from those who wish to disassociate themselves from it, the argument is made that ecofeminism, particularly in its social constructivist form, has been influential in international policy making. As a parallel development alongside feminist political ecology and other environmental feminisms it has developed analytically, infused by renewed interest by a new generation of academics and activists, as well as a new generation of environmental concerns, dominated by climate change.

Introduction

Ecofeminism, like the social movements it has emerged from, is both political activism and intellectual critique. Bringing together feminism and environmentalism, ecofeminism argues that the domination of women and the degradation of the environment are consequences of patriarchy and capitalism. Any strategy to address one must take into account its impact on the other so that women's equality should not be achieved at the expense of worsening the environment, and neither should environmental improvements be gained at the expense of women. Indeed, ecofeminism proposes that only by reversing current values, thereby privileging care and cooperation over more aggressive and dominating behaviors, can both society and environment benefit.

The notion that women's and environmental domination are linked has been developed in a number of ways. A perspective in which women are accredited with closer links with nature was celebrated in early ecofeminist writings, by, for example, Carolyn Merchant in the United States and Val Plumwood in Australia. These advocated 'the feminine principle' as an antidote to environmental destruction, through attributes, which nurture nature. This 'essentialist' perspective, often adopting an ideal of woman as earth mother/goddess, has, however, also discredited ecofeminism and led to disaffection among some early protagonists (see, for example, Janet Biehl). In addition to being critiqued for its essentialism, this view of ecofeminism has also been charged with elitism through its provenance in a white, middle-class, Western, milieu. However, Vandana Shiva's consistent and persuasive 'majority world' voice has been a counterpoint to this, and arguably, gender and environment have been articulated together more powerfully, and been more influential, in majority world settings (see, for example, Wangari Maathai in Kenya), although how this has been done has been questioned by writers such as Cecile Jackson and Melisssa Leach.

The late 1980s and early 1990s was a fertile time for ecofeminist writing, both from this essentialist perspective, but also through more social economic critiques, which explained the link between women's inequality and environmental degradation in terms of women's role in social reproduction (see, for example, Mary Mellor in the UK and Marilyn Waring in New Zealand).

The first major practical impact of ecofeminist thinking was felt in the 1992 United Nations Conference on Environment and Development (UNCED), which women's environmental organizations had lobbied for women's and environmental rights to be considered in tandem. This, and the 1995 4th Women's Conference in Beijing, agreed for the first time that women's rights and environmental rights could not be disentangled.

By the late 1990s, however, the output on ecofeminism had dropped significantly and there was a sense of it having run out of steam, despite its arguable influence revealed through UN initiatives. However, in the new millennium, a new generation of writers, researchers, and activists has reinvigorated ecofeminist debates, through considerations of ecofeminist citizenship (Sherilyn MacGregor), challenges to some earlier critiques (Niamh Moore), and insertion of feminist concerns into environmental justice (Susan Buckingham and Rakibe Kulcur, and Giovanna di Chiro) and political ecology (Wendy Harcourt, Dianne Rocheleau).

This article considers the heritage of ecofeminism as a multiply braided political praxis and an intellectual position. It examines key critiques of earlier perspectives, before exploring its more recent developments. It considers its relationship with, and potential to enhance other feminist and environmental approaches, particularly those concerned with feminist political ecology and environmental justice. The article concludes with a consideration of how ecofeminism is enjoying a resurgence through a new generation of academics seeking to develop and nuance ecofeminism from a sympathetic position, the emergence of climate change as a major global issue, and the development of social movements in areas not previously associated with feminist environmental action, notably in the Middle East.

A Brief History of Ecofeminism

Ecofeminism is not a singular position, and protagonists have emerged from different intellectual and political traditions. It is generally agreed that the first reference to 'ecofeminism' was by

the radical French feminist, Francoise d'Eaubonne, yet, despite her influence, particularly in North America and Australia, "Le féminisme ou la mort," (1974) and "Écologie, féminisme: révolution ou mutation?" (1978) have not been translated into English. It is also ironic, given that many of the Anglo-American/Anglo-Australian ecofeminists initially eschewed d'Eaubonne's Marxist–feminist analysis to focus on an essentialist/cultural approach.

Essentialism

This approach sought to reverse the Enlightenment/Cartesian hierarchy privileging a 'masculine' abstract rationality, which was seen to justify the exploitation of anything weaker than itself (colonial subjects, men without property, children, as well as women and the natural world). Thus, early ecofeminists elevated the 'feminine' principles of care and cooperation, not only to parity with the 'masculine,' but above it, on the basis that all human and nonhuman life would better thrive, guided by these principles (for example, Diamond and Orenstein, Merchant, and Plumwood). The most celebratory advocates of this approach (such as Mary Daly, Andree Collard, and Charlene Spretnak) argued that female biology tied women more closely to nature, primarily as they menstruated, and carried, gave birth to, and breastfed children. This, the cultural ecofeminists argued, enables women to make more sensitive decisions regarding humans' relationship with nature. The care needed to bear and nurture children and the households in which they develop provided the basis of an 'ethic of care' seen as necessary for the prevention of widespread environment destruction. This approach has been criticized on a number of grounds, as will emerge through this article, but one of the most persuasive is that for centuries, women have been relegated to the caring and domestic spheres precisely because of their essentialized biologies. It is not surprising, therefore, that many feminists argued that biology is insufficient grounds on which to determine justice, rights, and opportunities in any sphere.

Social Construction

More consistent with d'Eubonne's first articulation of ecofeminism has been the reasoning that women's typical work, socialized through generations, places them in more direct contact with nature. Whoever deals immediately with the social reproductive acts of provisioning, cooking, watering, clothing, cleaning and so on comes into daily contact with nature. This is most obvious in rural areas of the majority world where it is mostly women who walk to collect water, and biomass for cooking and heating water. Reliance on biomass for cooking on open stoves also makes women more vulnerable to respiratory diseases caused by indoor air pollution. It is also women who tend to be the subsistence farmers, and who therefore are most immediately impacted when structural adjustment policies require subsistence farmers to switch to cash crops, or where rights to harvest common land for wood, seeds, and other subsistence needs are suspended as the forest comes under national protection. It is these rural women's tasks, and their expertise as seed collectors, which Vandana Shiva has powerfully used in her ecofeminist analyses and campaigns against environmentally degrading practices, particularly in India. Likewise, Wangari Maathai, ecofeminist campaigner, academic and politician, drew on women's environmental knowledge and practices to develop the Green Belt tree planting movement in Kenya.

But the household division of labor is strikingly similar worldwide. Noted ecofeminist, and first woman and Green Party MP in New Zealand, Marilyn Waring, in her capacity as chair of the New Zealand Public Expenditure Select (Public Accounts and Budget) Committee, made a point of visiting women to inquire about their working day wherever she traveled. She was repeatedly struck by the ubiquitousness of women undertaking housework, caring for children and other dependents, and their relative lack of leisure time compared to men. A memorable vignette from a film made of her travels involved women in Tanzania giving a detailed account of their day, which started at sunrise to collect firewood and water, and ended with preparations for the next day's breakfast well after sunset. When Waring turned to a man standing at the edge of the group to ask him how he spent his day, his response that he 'supervised the women' drew much mirth. The persistent gendered vertical job segregation, wage inequalities, and distribution of caring responsibilities in the minority world, has stimulated a number of analyses, which link the exploitation of women with the exploitation of nature, through patriarchy and capitalism (see Mary Mellor, who, in her book 'Breaking Boundaries,' aspired to a 'feminist green socialism').

Challenges

The ecofeminist literature produced in the 1980s and early 1990s has been challenged on multiple fronts. Reference has already been made to the critique against essentialism. Both Gillian Rose (1993) and Val Plumwood (in her later work, 1993) questioned the wisdom of using what Plumwood terms an 'uncritical reversal' through which feminine virtues are elevated above masculine. Since the male/female duality is itself a product of 'masculinist' thinking, which has constructed the idea of the feminine it makes little sense to employ a product of such hegemonic construction. More recently, MacGregor questions the degree to which the feminine attributes invoked by ecofeminism are intrinsic, for "we simply do not know what 'feminine morality' would be under conditions of equity and freedom and we should not confuse actions shaped under socially oppressive conditions for 'natural' ones" (2004: p. 63).

Some ecofeminist writers have attempted to think beyond dualisms, particularly in their later work, and they do so by trying to rework the ethic of care into a concept which is beyond gender, and beyond duality. An example of this is Merchant's (1996) partnership ethic between men and women and Warren's (1994) prioritization of interpersonal relationships of mutuality. MacGregor would go further and jettison the concept of care as a foundation of ecofeminism in favor of a rights- and justice-based ethic of citizenship (I develop MacGregor's argument below). That she does so within the framework of ecofeminism is interesting, and contrasts with a position taken by Janet Biehl 13 years earlier. Writing from a social ecology position (to which she no longer adheres), in her 1991 book 'Rethinking Ecofeminist Politics,' Biehl publicly

renounced her ecofeminist past, arguing that, by denying aspects of Western culture, ecofeminism therefore "ignores or rejects legacies of democracy, of reason, and…the project of scientifically understanding much of the natural world as part of a radical liberatory movement" (1991: pp. 1, 2). These charges are leveled against an essentialist perspective and its internal contradictions and Biehl is clearly discomforted by what she sees as incoherence in a social movement, which needs to be "sorted out" (1991: p. 3). Her initial identification with ecofeminism stemmed from an attempt to show how women's concerns could be integrated into social ecology, which argues that the domination of nature is tied to hierarchies and class structures in human society. Dismantling these structures, she suggests, will "enable women to fulfil themselves completely, not only as gendered beings but as human beings" (1991: p. 5). While Biehl's frustration with the apparent incoherence of essentialist ecofeminism is understandable, her expectation that all self-proclaimed ecofeminists should be constructing a coherent argument, or battling out their differences in public could also be construed as trying to impose a rationality that ecofeminism itself challenges.

Iris Marion Young proposes that "essentialism is a dilemma for feminism" in that "if 'women' is not the name of a specific social collective, then there seems to be no basis for a specifically feminist politics. On the other hand, any attempt to define women as a group with common attributes either is absurdly reductionist or normalizes some of those meant to be included in the definition while marginalizing or excluding others" (1997: pp. 5, 6). While not written within the context of ecofeminism, this quote from a leading feminist philosopher emphasizes the difficulties related to essentialism, which cannot so easily be resolved by abandoning essentialism entirely as a form of analysis/praxis.

Since women's environmental roles have been recognized as a basis for policy by international organizations and development banks, partly as a result of ecofeminist writings, ecofeminism has drawn a sustained critique by a number of minority world academics working in the Global South, notably Cecile Jackson and Melissa Leach. In a reflection on her own work challenging ecofeminism, Leach castigates ecofeminism with failing to recognize the differences between women, and the risks to women of assigning them the "responsibility for 'saving the environment' without addressing whether they actually had the resources and capacity to do so" (2007: p. 72). This reading of ecofeminism: that it focused too much on women (rather than on gender relations), that it was overly simplistic, and that this had influenced a generation of development and environmental policies, has in turn been challenged (see Moore, 2008).

Leach had also argued that alternative lenses to viewing gender relations and their intersection with the environment, such as feminist environmentalism (as developed by Bina Agarwal) feminist political ecology (as articulated by Dianne Rocheleau) or gender, environment, and development (as propounded by Cecile Jackson) are superior to, and distinct from ecofeminism. However, these can also be seen as developments of a continuation of ecofeminist thinking, which is not fossilized in its 1980s form.

Since the 2000s there has been a more generous treatment of ecofeminism, which recognizes that it is not limited to the conceptualizations by its critics, and offers a starting point for further work. In 2007, Leach had herself noted that the critiques she and her colleagues had made may have contributed to a decline in women and gender relations being included in environment and development discourse.

Impacts of Ecofeminism

The inclusion of a chapter in Agenda 21 on the significance of women is an indication of the influence of ecofeminism in the early 1990s. This particular achievement was largely the result of successful lobbying of the UNCED (UNCED, 1992) by a coalition of women's groups brought together by Women's Environment and Development Organization (WEDO). Through the World Women's Congress for a Healthy Planet held in Miami in 1991, prominent groups and individuals, including some already well known for their ecofeminist perspectives, Wangari Maathai and Vandana Shiva, from both the Global North and Global South, developed a blueprint for women's involvement in environmental decision-making in 1991: Women's Action Agenda 21. This laid the foundation for considering women's rights at a number of international conferences in the 1990s. The 4th UN conference on women held in Beijing in 1995 also linked gender and environmental issues through its 'Action K,' which insisted on the integration of gender concerns into environmental decision-making, policies, and programs for sustainable development and assessments of development and environmental policies. Out of this emerged a UN (and EU) commitment to 'gender mainstreaming,' which requires all government policies and practices to take into account their gender impacts. How far these commitments have been enacted into national policies and practices, and whether they have made a difference to decision-making, is debatable. UN Women's assessment of how women's situation has changed as a result of the Millennium Development Goals reveals some positive, but very slow, change, as well as indications that women's involvement in decision-making influences the decisions taken. For example, UN Women reports that in female-led councils in India, the number of drinking water projects was 62% higher than in male-led councils. Climate change policy and decision-making has been resistant to reflecting gender concerns. Nevertheless, in 2012, the annual meeting of the conference of the parties (COP18 in Doha) recognized the importance of gender balance in formal and informal decision-making to enact more effective climate change policy, and agreed to set targets to achieve this. This follows a number of initiatives set up by European governments to achieve minimum quotas of women on corporate boards, post-2000, although sectors most implicated in environmental problems (such as transport, waste, energy, water) have some of the lowest proportions of women on their boards.

Arguably, then, ecofeminism, alongside broader feminist campaigns, has been influential in environmentally related policy, at least internationally. In terms of its influence in other environmental movements, ecofeminism has failed to make significant impacts, although there are indications of its capacity to do so in more recent work by proponents who stress their ecofeminist heritage.

Ecofeminism in Other Environmentalisms

In many ways the environmental movement remains resolutely masculine, white, and middle class. This had been observed in the United States by Joni Seager in the 1990s when she reported on the lack of women (not to mention women of color) in the mainstream North American environmental movement. There is public acknowledgment that company boards in the UK and scientific research are hampered by a dominant masculinity and that more evenly mixed gender composition will generate more diverse and effective decision-making by incorporating a variety of male and female perspectives (European Commission, 2012; UK Government, 2011). However, this has not percolated through to the environmental movement, which is still characterized by a culture of long hours, inflexible working practices, and a masculinist culture, well revealed by Rakibe Kulcur in the UK and Turkey. As will be discussed later, Iris Marion Young calls into question existing decision-making structures and argues for these to be transformed into bodies in which men and women can communicate effectively with each other in nondiscriminatory ways.

The Gender Justice in Environmental Justice?

The environmental justice movement has run parallel to the ecofeminist movement since the 1980s and also involves advocacy and an intellectual analysis of how disadvantaged populations are disproportionately exposed to environmental problems. This has been revealed at a global scale, through ways in which the global north 'dumps' on the global south, but has been particularly powerful in exposing the environmental racism against African-American and Hispanic communities in the United States. However, with notably few exceptions, gender is given no room in these analyses. Those case studies, which do focus on women's experiences of environmental injustice draw, both implicitly and explicitly, on ecofeminism, particularly through women's roles in the household and community. Lois Gibbs' through her celebrated campaign against governments failing to recognize the evidence she collected regarding the industrial pollution of a local school and increased rates of cancer and other diseases of her family and neighbors has become a 'poster child' of the environmental justice movement. However, a gender analysis of other environmental injustices is rare (but see Hilda Kurtz and Judy Sze for exceptions). Judy Sze has related how African-American lone mothers in New York's Harlem were castigated by City Hall as being poor mothers and housewives when they made complaints about the polluted streets they suspected of causing increased rates of asthma among their children (Sze, 2004). Both Gibbs and Kurtz report women's concerns being dismissed by city officials as those of 'hysterical housewives.' The environmental justice movement, then, like the environmental movement more generally, is not sufficiently sensitive to gender.

Interestingly, academics such as David Schlosberg and Gordon Walker have drawn on the writings of feminist philosopher Iris Marion Young (1990) in developing a theoretical analysis of environmental justice, which goes beyond the distributional, to include representative and participative justice. However, her deeper critique, which analyses gender relations through the concepts of domination and oppression, rather than the concept of distribution, finds little expression in environmental justice. While environmental justice is not a term Young uses, she writes extensively on women's health and reproductive rights, which Giovanna di Chiro argues constitute a legitimate concern for environmental justice activity, in a broad sense. Di Chiro detects a masculinism in mainstream environment movements, which generates silos in which 'environment' is constructed as something other than the human and the social, thereby excluding a lot of 'environmental' concerns and activism of women involved in, for example, the reproductive rights movement (Di Chiro, 2008: p. 279).

Feminist Political Ecology

Melissa Leach, in dismissing ecofeminism, suggests that feminist political ecology was framed as an alternative perspective to ecofeminism. In their 1996 book *Feminist Political Ecology*, Dianne Rocheleau, Barbara Thomas-Slayter, and Esther Wangari are less dismissive, setting out their aim as "an explicit effort to join feminist and political ecology scholarship from the ground up, based on case studies compiled from collaborative field research or direct participation in the events recounted" (1996: p. xvi). The authors identify ecofeminism as one of five "major schools of feminist scholarship and activism on the environment," on which they seek to draw to explicate a "new conceptual framework, which we call feminist political ecology" (p. 3). However, the divisions between the five (the other four of which are feminist environmentalism, socialist feminism, feminist poststructuralism, and environmentalism) are not clear. Even in the early 1990s, writers such as Mary Mellor and Ariel Salleh, writing in Capital, Class and Nature, were crossing these boundaries. This feminist political ecology 'manifesto' can be seen as calling for the contextualizing of ways in which different women, and groups of women, experienced the 'environment,' which writers identifying as ecofeminists are now doing (see, for example, MacGregor, below).

Feminist political ecologist, Wendy Harcourt, pays particular attention to the body as "the place closest in" (2009: p. 22) and argues that the women she has worked with in social movements are "keenly aware of the conditions of their embodiment, including health, sexuality, security, the right to pleasure and rest, and the need to care for community and environment…". As women mobilize for change around the body, home, local environs, and community, Arturo Escobar and Wendy Harcourt argued they were creating a form of politics, they called 'place based,' with the body as the first "place" (p. 23). While not expressly referring to ecofeminism, this position is a strong echo of it, and has much to offer it.

The Future for Ecofeminism?

Following a period of high profile activism in the late 1980s and early/mid-1990s, during which ecofeminism appeared to have influence on the international development and environmental agenda, it fell out of favor. Unfairly, perhaps,

accused of the essentialism, which characterized some, but by no means all, of its early expression, the number of ecofeminist publications dropped, and ecofeminists seemed unable to respond effectively to challenges. More recently, however, younger writers have declared a sympathy with the approach and, while not uncritical of earlier ecofeminist writing, have chosen to see this as a starting point for a sustained feminist critique of environmental problems.

Ecofeminist Citizenship

Sherilyn MacGregor (2004) has argued that ecofeminism's emphasis on 'caring' relegates this to the private and 'nonpolitical' realm. A failure to engage in the politics of social reproduction maintains the fundamental divisions of labor, and reifies women's work, and therefore gender inequality. While recognizing the achievement of ecofeminism in inserting care work, conducted in the private sphere of the home, and the intermediate community sphere, into ecopolitical discourses, which had hitherto ignored it, MacGregor pushes ecofeminism to relate to broader theories of justice (see also Catriona Sandilands). MacGregor argues, after Joan Tronto, and also implicitly following Carolyn Merchant, for care "to be seen as integral to any notion of a good society" (MacGregor, 2004: 75) and therefore part of everyone's remit. Women's relationship to caring and domestic work is further complicated by class and income and it is important to note that the 'equity and freedom' of some women to enter the paid/market economy is predicated on being able to employ other women to undertake the care work, often on the margins of a livable wage, previously undertaken unpaid (Gregson and Lowe, 1994).

Notwithstanding MacGregor, care work has been politicized, with writer-campaigner Selma James' 'International Wages for Housework' campaign launched in 1972 to demand recognition that housework is a foundation for paid work in the market economy. Arguably, the most intimate of exchange, sex, can also be a political commodity, withheld to achieve political ends. In one of a long line of such campaigns, dating back to ancient Greece, women in Barbacoas in Colombia have been reported in the Washington Post as using sex as a public bargaining strategy: in this case, refusing sex with their partners until repairs have been made to a road frequently impassable, particularly in bad weather.

Climate Change

Increasing attention to climate change through the 2000s has also generated interest in its governing structures and it can be noted that gender forms an extremely small and marginalized part of the debate, compared to that on sustainable development in the 1990s. However, WEDO was a partner in a campaign, GenderCC, to ensure that gender is taken into account in climate change decision-making, mitigation, and adaptation. A recent milestone was achieved at the 18th meeting of the Conference of the Parties (COP18) in Doha, which adopted a decision on "promoting gender balance and improving the participation of women in UNFCCC negotiations and in the representation of Parties in bodies established pursuant to the Convention or the Kyoto Protocol" (UNFCCC, 2012).

Joni Seager, writing in a special issue of *Women, Gender and Research* (a Danish journal published in English) in 2009 ahead of the Copenhagen climate change summit, castigates the political and scientific communities for "[o]ne of the core illusions of the 2° target" suggesting that "humans can 'master' climate change, allowing the global temperature to rise to an arbitrary line and then stopping it" (2009: p. 14). Citing earlier ecofeminists such as Merchant, Plumwood and Warren, Seager invokes their 'trenchant analyses' of attitudes such as this. Ecofeminism has also been cited as an explicit organizing concept in environmental and climate change law articles and books (Morrow, 2012), suggesting a widening of ecofeminism's influence a decade into the twenty-first century.

Activism

Prodemocracy movements that defined the 'Arab Spring' in 2011/2012 have included a number of campaigns which Green Prophet (a Website claiming to be the 'sustainable news for the Middle East') have branded as 'ecofeminism.' These range from the more conventionally environmentalist solar power projects, in which Bedouin women in Jordan are installing solar panels in desert communities, to those 'crossover' projects described by di Chiro as integrating social and environmental issues, often ignored by the environmental mainstream, including a 'harass map' to enable women cyclists in Cairo to report abuse while cycling, through SMS.

Meanwhile, women in Colombia, Nigeria, and the United States have protested against decisions to exploit communities and the environment, using their bodies (threatening to strip naked, disrobing, or withholding sex from their partners) and language that would be familiar to earlier ecofeminists (see Websites below).

In Conclusion

It is possible to argue that ecofeminism has survived and evolved from its inception in the 1970s and 1980s. Activists and a new generation of academics cite ecofeminism as an inspiration, and seek to clarify and strengthen its arguments through more empirical and case study work, and multidisciplinary analysis. Some critiques of ecofeminism in the mid- and late-1990s into the 2000s could be accused of being antifeminist in their apparent ungenerous and undermining attempts to challenge masculinist hegemonic thinking. However, those seeking to distance themselves from ecofeminism have, in turn, stimulated debate and development, including a defense of ecofeminism and a willingness to critique it in more constructive and inclusive ways. While ecofeminist organizations and alliances have gained some influence in international policy, it is also clear that gender inequality and environmental degradation continue and in some cases have worsened, revealing the continued need for an ecofeminist analysis.

Ecological Economics

Joan Martinez-Alier, After Universitat Autonoma de Barcelona, Barcelona, Spain; and FLACSO, Quito, Ecuador

Abstract

Ecological economics was constituted in the late 1980 as a transdisciplinary field of study attracting systems ecologists and dissident economists. Inspiration was drawn from N. Georgescu-Roegen's *The EntropyLaw and the Economic Process* (1971) together with work from ecologist H.T. Odum and economist K. Boulding. The complexity of living structures is achieved by 'capturing' energy through photosynthesis and by dissipating energy to outside systems. The industrial economy, however, does not work only by using current photosynthesis. It burns irreplaceable stocks of fossil fuels, and it produces irreversible damage to the natural environment. The scale of the economy is too large; therefore the natural cycles cannot sustainably produce the resources, or absorb or assimilate the waste such as, for instance, heavy metals or excessive carbon dioxide. Ecological economics encompasses money valuation of positive environmental services and of negative externalities, and also physical appraisals of the environmental impacts of the human economy measured through new indicators. It also gives importance to social indicators. The study of the relations between property rights and management of natural resources is another important focus. Ecological economics favors multicriteria assessments over cost–benefit analysis, emphasizing incommensurability of values. It has also developed an ecological macroeconomics without growth.

Introduction: The Economy Embedded in Society and Nature

Ecological economics is a transdisciplinary field of study which sees the economy as a subsystem of a larger finite global ecosystem. Ecological economists question the sustainability of the economy because of its environmental impacts and material and energy requirements, and also because of the growth of population. Attempts at assigning money values to environmental services and losses thereby correcting macroeconomic accounting, are part of ecological economics, but its main thrust is rather in introducing physical indicators and indices of sustainability. Ecological economists also work on the relations between property rights and resource management, they model the interactions between the economy and the environment, they study ecological distribution conflicts, they use management tools such as integrated environmental assessment and multicriteria decision aids, and they propose new instruments of environmental policy.

From the beginning of ecological economics (Daly, 1984), there was a debate between three approaches. First, to go beyond the mere description of the human economy in ecological terms (flows of energy and materials, evolution of technologies in analogy to biological evolution) and search for a physical common value (such as energy value). Second, to follow the strategy of hanging a price tag on everything, using fictitious market prices when actual market prices are lacking. While the first and second approaches are reductionist, the third approach is not reductionist but transdisciplinary.

René Passet in 1979 in *L'économique et le vivant* drew an image of the relations between nature, human society, and the human economy (Figure 1) that has become a symbol for ecological economics. The drawing shows the obvious reality that there was nature before human society, and human society preceded the generalized market system by many generations. This vision has implications for economics. The teaching of the theory of externalities (i.e., the impacts of the economy on the environment which are not measured by market prices) should not wait for the time when students have grasped already the analysis of general market equilibrium. On the contrary, the study of the market (the chrematistics) should come after the study of ecology and social institutions. The 'externalities' come before the 'internalities'. The market economy could not exist

Figure 1 The economy embedded in the institutions of human society and in the biosphere.

without social institutions, and without the unpaid products and services of ecosystems.

Ecological economists see the economy as an open system. In thermodynamics, systems are classified as 'open' to the entry and exit of energy and materials, 'closed' to the entry and exit of materials though open to the entry and exit of energy, such as the Earth, and 'isolated' systems (without entry or exit of energy and materials). The availability of free energy and the cycling of materials allow life forms to become ever more organized and complex; the same applies to the economy. Dissipated energy and waste are produced in the process. If the scale of the economy is too large and its speed is too rapid, then the natural cycles cannot sustainably produce the resources or absorb or assimilate the waste such as, for instance, heavy metals or carbon dioxide.

In ecological economics the economy is seen as embedded in the ecosystem (or, more accurately, in the historically changing social perception of the ecosystem). The economy is also embedded in a structure of property rights on environmental resources and services, in a social distribution of power and income, in social structures of gender, social class, or caste. Instead, in mainstream economics the economy is seen as a self-sufficient system where prices for consumer goods and services and those for the services of production factors are formed.

Ecological economists (Norgaard, 1990) disputed the view expressed in the 1960s by Barnett, Krutilla, and other mainstream resource economists that since raw materials were cheap, they must be abundant. Markets are myopic; they discount the future, they cannot see future uncertain scarcities of sources or sinks. Ecological economists understand and even sympathize with attempts at 'internalizing' externalities into the price system, they readily concur with proposals to correct prices by taxes (such as 'natural capital depletion taxes' or taxes on pollution) but they deny that there exists a set of 'ecologically correct prices'.

History and Foundations

In the late nineteenth and early twentieth centuries, the biologist and urban planner Patrick Geddes, the chemist Frederick Soddy, the engineer and social reformer Josef Popper-Lynkeus had unsuccessfully tried to promote a biophysical view of the economy, as a subsystem embedded in a larger system subject to the laws of thermodynamics (Martinez-Alier and Schlüpmann, 1987). By 1850 or 1860 the carbon cycle and the cycles of plant nutrients had been discovered, while the first and second laws of thermodynamics (conservation and transformation of energy, but also dissipation of energy and increase in entropy) had been established.

The contrived conflict between the 'optimistic' theory of evolution, which explained the diversity of life, and the 'pessimistic' second law of thermodynamics was a staple of the cultural diet of the early 1900s. Praising the energy accounts of agriculture published in 1880 by the 'narodnik' revolutionary and physician S.A. Podolinsky, the ecologist Vernadsky wrote in 1924 (Vernadsky, 1924: pp. 334–335) that Podolinsky had analyzed the energetics of life (life systems being open to the entry of energy), and had applied these ideas to the analysis of the economy. Podolinsky wrote that, for an economy to be sustainable, the energy productivity of human work (i.e., how much energy is made available by 1 day of human work) must be higher (or equal, if everybody is working) than the efficiency of the transformation of the energy intake into human work. The energy productivity of a coal miner (wrote Podolinsky) was much larger than that of an agriculturalist could obtain but this energy surplus from fossil fuels was transitory (Podolinsky, 1880, 1883).

Therefore, the main ingredients for an ecological view of the economy were present much before the birth of a self-conscious ecological economics in the 1980s, which was delayed by the strict boundaries between the natural and the social sciences. The biologist and systems ecologist Alfred Lotka, born in 1880, had introduced in the 1910s and early 1920s the fundamental distinction between the endosomatic and exosomatic use of energy by humans. While we have genetic instructions on the amount of food energy to be consumed (about 7–10 MJ per day for an adult), our exosomatic use of energy depends on culture and income, and reaches 1 GJ or more per day for rich people.

Much later, four well-known economists, who did not yet form a school, are seen in retrospect as ecological economists: Nicholas Georgescu-Roegen (1906–94), the author of *The Entropy Law and the Economic Process* (1971) (where Lotka was often quoted), Kenneth Boulding (1910–93), who worked mainly on general systems analysis, K.W. Kapp (1910–76) and S. von Ciriacy-Wantrup (1906–80), who were both institutionalist economists. The systems ecologist H.T. Odum (1924–2002) studied the use of energy in the economy and some of his former students were among the first ecological economists in the 1980s. Other sources of ecological economics are in Environmental and Resource Economics (microeconomics applied to environmental pollution and the depletion of natural resources), in Human Ecology, Ecological Anthropology, Agroecology and Urban Ecology, and in the study of 'industrial metabolism' as developed by Robert Ayres (born in 1932), now known as Industrial Ecology.

The first books or special issues of journals with the title 'Ecological Economics' appeared in 1987. After meetings in Stockholm and Barcelona with a large group of ecologists and economists, Robert Costanza and Herman Daly set up the International Society for Ecological Economics (ISEE) and convened the first world conference in Washington, DC, in 1990. The book that came out of this first conference (Costanza, 1991) ambitiously defined the field as 'the science and management of sustainability'. The successful academic journal *Ecological Economics*, started in 1989, was edited first by Robert Costanza, and later by Cutler Cleveland (who also edits the Encyclopedia of the Earth) and Richard Howarth.

Some environmental economists of neoclassical persuasion were also present in those early efforts. David Pearce became one of the main editors of the new journal, *Ecological Economics*, but he left the journal after 1994 because of internal disputes on what is now called 'weak sustainability vs strong sustainability'. Pearce had influenced the World Bank to do macroeconomic accounts in which 'human-made capital' could in theory substitute for so-called natural capital. This was 'weak sustainability', i.e., sustainability in the weak sense of the

term. Herman Daly, Peter Victor, and other ecological economists objected to 'weak sustainability'. One could not sustainably substitute the increased horsepower of the fishing fleet for a declining availability of fish. Moreover, measurement of stocks of capital depended on the rate of profit (as discussed in the controversies on capital theory of the 1970s) (Victor, 1991).

However, the ISEE is a scientific society encouraging internal controversy and also a product of the environmental movement of the 1960s and 1970s in its different varieties. Internal pluralism and perhaps some confusion of ideas were present in the volume produced after a second ISEE conference in Stockholm in 1992, *Investing in Natural Capital: the Ecological Economics Approach to Sustainability*. While some ecological economists feel even today that the metaphor of 'natural capital' is useful, others strongly reject it because it suggests that we can use 'units of capital' as a common measuring rod that would make commensurable the losses of biodiversity and the increases in manufactured capital stocks. The notion of 'natural capital' supports policies such as 'habitat trading' (one habitat is destroyed and another one, far away, is effectively protected) or the Rio Tinto mining company's doctrine of 'net positive impact' (a new location is destroyed while another is preserved and enhanced, going round the world until no natural spaces would be left).

While H.T. Odum (and his disciples working on human ecological energetics: A.M. Jansson, Robert Costanza, Charles Hall, Cutler Cleveland), David Pimentel with Mario Giampietro (agricultural energetics), and C.S. Holling ('resilience') were the ecologist grandfathers, mothers, and fathers of ecological economics. K. Boulding and N. Georgescu-Roegen were the economist grandfathers. (K.W. Kapp had died early, missing the birth of ecological economics.) Herman Daly's influence was also decisive. Daly (born in 1938) published his first article in what we now call ecological economics in 1968 in *The Journal of Political Ecology*. In the early 1990s (Daly and Cobb, 1989), he promoted an index of sustainable economic welfare (ISEW) expressed in money terms that showed results very different from GDP (because of the different assumptions in the calculations). It seemed at the time that ISEW was a good way to attack GDP accounting but an index in money terms was not congruent with the critique against 'weak sustainability'. Daly maintained his stature in the field and recently increased it as his early defense of a steady-state economy (Daly, 1973) is now seen as having announced the new ecological macroeconomics without growth (Victor, 2008; Jackson, 2009).

Daly was explicitly inspired in his work by Boulding and Georgescu Roegen. Boulding had published a famous article on *The Economics of the Coming Spaceship Earth* (a spaceship where materials would have to be recycled) (Boulding, 1966). He became a card-carrying member of the ISEE and an author in the collective book edited by Costanza (1991). Georgescu-Roegen refused to be drawn into the ISEE; he preferred to call the field 'Bioeconomics' (Mayumi, 2001; Bonaiuti, 2011) and announced the publication of a book with this title that never appeared. He disliked Costanza's article in *Science* in 1980 (Costanza, 1980) proposing an energy theory of value, he also disliked H.T. Odum's 'Emergy' (embodied energy) accounts to which he answered with an irritated reply: 'matter matters too' (Georgescu-Roegen, 1977) against what he called the 'energetic dogma'. On the other hand, Boulding, more concerned with scarcity of materials than with energy dissipation, wrote a less than enthusiastic review of Georgescu-Roegen's magnum opus. In due course the edition of the collected works and correspondence of such major intellectual figures and pioneers of ecological economics will clarify the real substance, if any, in such disagreements and quarrels.

Georgescu-Roegen's point on the importance of entropy for the economy is as follows. Life is 'negentropic': Georgescu cited very often Schrödinger's *What Is Life* (1944). The evolution of species, the complexity of living structures, was achieved by 'capturing' energy through photosynthesis, and by dissipating energy to outside systems. The industrial economy, however, after the thermo-industrial revolution (Grinevald, 1976) did not work only by using current photosynthesis or hydraulic energy. It was burning stocks of fossil fuels. Even a nongrowing industrial economy would not be sustainable because energy cannot be used twice (except in minor cases of 'cogeneration'). In any day in 2014 we take 90 million of barrels of oil from the 'subterranean forest' (Sieferle, 2001), tomorrow we do the same again, a little more or a little less, whether from the bottom of the sea or from fields in Iraq or Saudi Arabia, the rainforest of Ecuador or the Orinoco Delta in Venezuela. Perhaps the energy return on energy input (EROI) is declining (the energy return on the energy input) or perhaps not yet, Georgescu was also very aware of the approaching Hubbert's 'peak oil'.

Although we could claim that Darwin won against Sadi Carnot (Prigogine and Stengers, 1984), in the industrial economy the sources of low entropy become scarcer. Moreover, materials cannot (in practice) be recycled to the full extent (an observation that Georgescu tried to glorify into a fourth law of thermodynamics, without success, Mayumi, 2001). Georgescu saw the economy as a system open not only to the entry of energy and materials but also to the unavoidable exit of inconvenient and unrecyclable 'garbojunk' (a word formed by garbage + junk).

Georgescu's fundamental contribution to ecological economics was then that, because of the second law of thermodynamics or entropy law, even a nongrowing industrial economy is not sustainable. Therefore, in the rich economies, a 'steady state' (as proposed by Daly, drawing on Stuart Mill), would not be enough. A steady-state economy aims for mildly fluctuating levels in population and consumption of energy and materials. Birth rates equal death rates, and (in economic terms) saving/investment equals depreciation. Georgescu said that in rich countries a degrowth in the inputs of fossil fuels and other materials was required. Hence Georgescu's agreement to the French title to a selection of his articles edited by Grinevald in 1979, *Demain la Décroissance*. In retrospect, this book became one main inspiration for the European 'degrowth' movement after 25 years (Martinez-Alier et al., 2010). Nobody ever preached a 100% degrowth of the economy. Georgescu's lower limit would be that of an economy fueled by the current inflow of solar power. There is therefore a confluence of ideas between Georgescu's degrowth, Daly's steady state (Kerschner, 2010) and the new ecological macroeconomics without growth.

Apart from the United States and Europe, the Japanese 'entropy school' of economic analysis (Tamanoi et al., 1984) studied the environmental services provided by the water cycle, and also the ancient urban ecosystems of Japan. In India, there was much work since the 1970s not only by economists but also by ecologists (Madhav Gadgil) on the links between forest or water management and common property rights, nowadays one main focus of interest in ecological economics (Berkes and Folke, 1998; Agarwal, 2010). Other early ecological economists (whose major works were not in English) are, in France, Rene Passet (1979) and Ignacy Sachs who proposed in the early 1970s the notion of 'eco-development'; Roefie Hueting (1980) in the Netherlands and Christian Leipert in Germany; and Jose-Manuel Naredo in Spain (Naredo, 1987). (For general introductions to the field: Costanza et al., 1997b; Cleveland et al., 2001; Martinez-Alier and Røpke, 2008; Spash, 2009).

A New Ecological Macroeconomics without Growth

Keynesian macroeconomics' initial concern was the 'short term'. One prescription for times of economic crisis was increased 'deficit spending' (increasing the public debt) to finance public expenditure thereby increasing employment, to compensate for the decline in private investment that caused the economic crisis. However, such public investment would by itself increase the productive capacity of the economy; therefore in the long run there was a need to increase again aggregate demand. Keynesianism became a doctrine of continuous economic growth through the Harrod-Domar models of the 1950s. In 2008–09, a new ecological macroeconomics without growth made a breakthrough in public opinion, due to two ecological economists of long standing, Peter Victor and Tim Jackson. A Keynesian-inspired macroeconomics without economic growth is a novelty that ecological economists are offering the world. Ecological economists had previously tried to engage with Keynesian and post-Keynesian economics (Daly and Farley, 2010; Holt et al., 2009) and there was also the tradition of a steady-state economics.

Peter Victor gives several reasons why a country like Canada should no longer have economic growth. Economic growth as measured by changes in GDP is inextricably related to increases in materials and energy despite gains in efficiency over time. The historical record shows a positive link between economic growth and increasing flows of materials and energy (measured as work done, Ayres and Warr, 2009). In fact, gains in efficiency sometimes contribute to increased material and energy throughput because of the operation of Jevons' Paradox, also known as the 'rebound effect'.

How could we manage without growth, at least in advanced economies? These economies are very wealthy as measured by consumptions standards but happiness or life satisfaction has not increased pari passu with income and consumption. The so-called Easterlin's Paradox states that life satisfaction does not grow above a certain level of income, perhaps US $15 000 per capita per year.

Through simulation models Victor then shows that a nongrowing economy in Canada could maintain life satisfaction, achieve nearly full employment, eliminate poverty, and significantly reduce greenhouse gas (GHG) emissions. Simultaneously, the weight of the public debt relative to GDP would decrease. Perhaps more than the results, which depend as usual on the assumptions of the models, the striking novelty is Victor's question itself, "is managing without growth possible?" (2008).

Meanwhile, Tim Jackson wrote a report for the British government in 2008 with the title: *Prosperity without Growth?* (Jackson, 2009). He argued that consumer debt had increased far too much before the economic crisis of 2008 while the public debt would be increasing enormously after 2008 in many countries. Debts can be settled by inflation (money loses value), or by impoverishing the debtors (what some Greeks call 'debtocracy', creditors' rule), or by economic growth. Here Jackson recalls again not only the well known critiques of GDP but also the research on Easterlin's Paradox.

Jackson asked repeatedly for 'financial prudence', not only because of the risk of default but even more because debt repayment requires economic growth, and growth in rich countries is to be avoided for ecological and social reasons. The ecological reasons are clear. If world trends of 2007 would continue, then in order to keep carbon dioxide concentration below 450 ppm, the carbon intensity of the rich economies would have to decrease over 100 times by 2050. This seems impossible. The greenhouse effect was emphasized by Jackson more than 'peak oil' and other planetary boundaries such as biodiversity loss. It sufficed him to make the point.

The development of human potential should not and cannot be achieved by increased consumption of 'positional goods'. Therefore, stopping economic growth is sound from the ecological and economic viewpoints and also socially. Lack of growth requires a revaluation of the goods and services we can get from the commons without damaging the welfare of other people. Jackson gives then policy recommendations based on this ecological macroeconomics. If there is no economic growth, unemployment will increase, given the trend to increased labor productivity because of technical change and the drive for profits. While André Gorz shockingly said *adieu au prolétariat* already in 1980 (not in China or India but in Europe), Jackson is concerned with 'the stigma of unemployment'. Hence, support must be given to the so-called Cinderella sector (which, remembering William Morris, one could call the 'News from Nowhere' sector). This sounds naïf but it is well thought out. One virtue of this sector is precisely low labor productivity and the capacity to give massive useful employment. Jackson's other policies are a basic universal citizen's income and work sharing, and also investments in renewable energy and in ecosystem restoration and enhancement. Since such investments are unlikely to give a high rate of return in money terms, the share of savings (or taxes) and the role of the public sector of the economy will have to grow. Does this mean a retrenchment of capitalism? Do not get excited about words, is Jackson's motto. But the question remains whether a nongrowing capitalist system is possible at all.

Financial Debts Compared to Real Wealth

The amount of real wealth that an economy can create is limited by the amount of low-entropy energy and materials

that it can sustainably take from the external environment, and by the amount of effluents such as the GHGs that the environment can sustainably absorb. Jackson's 'financial prudence' is not a new doctrine in ecological economics, on the contrary. The Nobel Prize in Chemistry and expert on radioactivity Frederick Soddy wrote on energy and the economy from 1910 onward. He compared 'real wealth' which grows at the rhythms of nature and which, if turned into manufactured capital, is worn down, with 'virtual wealth' in the form of debts which apparently could grow forever. Private property in a capitalist system guarantees (for a while) the increasing private debt while the public debt could apparently grow based on the guarantees provided by the State. But this was a flimsy building.

Soddy was quoted by Daly and other ecological economists since the 1980s, much before the financial crisis of 2008. Debt-fueled growth was not viable. The real fuel of economic growth was coal, oil, gas. Yes, life is negentropic but even eucalyptus cannot grow for more than 30 years at 10% per year. Then they stop growing. Soddy's book of 1926 was called *Debt, Wealth and Virtual Wealth*. He drew on John Ruskin. He meant that debt was not real wealth, it was virtual wealth. Real wealth was the current inputs of solar energy. Although ecological economists have not developed a consensual monetary reform plan, they follow Soddy on the need for 'financial prudence' recommending for instance a large increase in the cash reserve requirements of banks (Daly and Cobb, 1989).

Soddy approvingly quoted Aristotle's distinction between Oikonomia and Chrematistika, as Marx had done and Karl Polanyi (1957) was to do later. Ecological economists are fond of this distinction. Oikonomia meant the study of the material provisioning of the oikos (the extended family) while chrematistics was the art of studying market prices to make money, for instance by becoming a monopolist (a word used by Aristotle). What Aristotle called oikonomia would now be called human ecology and economic anthropology, while chrematistics is what students of microeconomics learn.

Irreducibility of Needs

In economic theories of production and consumption, compensation and substitution reign supreme. Not so in ecological economics, where diverse standards of value are deployed 'to take nature into account' (O'Connor and Spash, 1999). In the ecological economics theory of consumption, some goods are more important and cannot be substituted by other goods (economists call this a 'lexicographic' order of preferences). Thus, sacredness cannot be traded off. And no other good can substitute or compensate for the minimum amount of endosomatic energy or for water necessary for human life. To call either the endosomatic consumption or the exosomatic use of energy a 'socially constructed need or want' would leave aside the ecological explanations and/or implications of such use of energy, while to call the daily endosomatic consumption a revealed preference would betray the conventional economist's metaphysical viewpoint.

There is another approach which, as pointed out by John Gowdy and Susan Mesner (1998), builds upon the 'principle of irreducibility of needs' (proclaimed by Georgescu-Roegen in the 1968 edition of the Encyclopedia of the Social Sciences, article on 'Utility'). According to Max-Neef (Max-Neef, 1992) all humans have the same needs, described as 'subsistence', 'affection', 'protection', 'understanding', 'participation', 'leisure', 'creation', 'identity', 'freedom', and so on and there is no generalized principle of substitution among them. Such needs can be satisfied by a variety of 'satisfactors'. Instead of taking the economic production as given, we may ask (as in the steady state and *Décroissance* perspectives) why is there so much travel, why so much building of houses with new materials instead of restoration of old ones… Is there a trend to use 'satisfactors' increasingly intensive in energy and materials in order to satisfy predominantly nonmaterial needs?

Against Commensuration

One of the foundations of ecological economics is incommensurability of values although ecological economists understand and have pushed sometimes for the economic valuation of ecosystem services, with the avowed intention of making them more visible to the general public and to policy makers who are assumed to think mainly in money terms. Nevertheless, the insistence on money valuation clearly makes less visible the biological and ecological importance of nature, and also livelihood and cultural values. The beauty and sacredness of a mountain such as the Niyamgiri Hill in Odisha might seem negligible when compared to the very large money value of its bauxite deposits. The mountain is better defended outside money valuation (Temper and Martinez-Alier, 2013). The debates on when is money valuation appropriate continue in ecological economics (Kumar, 2010). A consensus is perhaps being reached that money valuation is appropriate when trying to make companies accountable in civil litigation for their past environmental liabilities (as in the British Petroleum case in the Gulf of Mexico, Chevron-Texaco in Ecuador, or Shell in the Niger Delta) but it is not appropriate for taking decisions for the future (whether on climate change or biodiversity policies or on building an open cast mine or a dam), when money valuation becomes only one of several relevant valuation languages.

In evaluating investment projects, ecological economics favors participatory multicriteria evaluation (Munda, 2008) and deliberative methods (Zografos and Howarth, 2008) over cost–benefit analysis (CBA). This is not only because of 'technical' problems with CBA (which discount rate to use, which methods of money valuation to apply to nonmarket goods and services or to negative 'externalities') but mainly because of a political question: Who has the power or the right to simplify complexity by imposing a single valuation language? Most ecological economists (but not all) would side with Spash (2007, 2011) in his vigorous critiques against the CBA approach of the Stern review on climate change and against the UNEP TEEB project (*The Economics of Ecosystems and Biodiversity*), and also in his call for an ecological economics that definitively breaks away from neoclassical environmental and resource economics (Spash, 2012).

Debates on fictitious money valuation and weak sustainability have accompanied ecological economics from its

inception. In the early years, the identity of this field that considers the economy as a subsystem of the environment, and not as the simple application of conventional economics to environmental issues (as in 'transport economics' or 'agricultural economics'), was preserved through episodes such as David Pearce's withdrawal as one main editor of the journal and Daly's resignation from the board of the Beijer Institute in Stockholm that had given itself the name of 'ecological economics' while promoting mainstream economists.

In the 1990s, there remained however in the Beijer Institute of Ecological Economics, as a junior researcher, one of A.M. Jansson's students, the ecologist Carl Folke (H.T. Odum's intellectual 'grandson' so to speak). In due course the Resilience Alliance was born in Stockholm with C.S. Holling's support. The notion of resilience (the capacity of a system to withstand or recuperate from disruption) came to dominate in ecology and in ecological economics over the simpler notion of carrying capacity.

Ecological economics is not committed to a unique type of value expressed in a single numeraire or unit of account. "The issue is not whether it is only the market place that can determine value, for economists have long debated other means of valuation; our concern is with the assumption that in any dialogue, all valuations or 'numeraires' should be reducible to a single one-dimension standard" (Funtowicz and Ravetz, 1994: p. 198). Ecological economics encompasses money-valuation, and also physical appraisals of the environmental impacts of the human economy measured in their own physical numeraires. It also gives importance to social indicators.

Nature provides resources for the production of commodities and it also provides environmental amenities. As shown by Gretchen Daily (1997), De Groot (1992) and other authors, nature, more importantly, gives gratis essential life-support services such as the cycling of nutrients, the water cycle, soil formation, climate regulation, conservation and evolution of biodiversity, concentration of minerals, dispersal or assimilation of pollutants, and diverse forms of useful energy. Controversial attempts have been made to assign money values to the annual flows of environmental services, to compare them to GDP in monetary units of account (Costanza et al., 1997). For instance, the cycling of nutrients (nitrogen, phosphorous) in some natural systems may be given a plausible money value by comparison with the costs of alternative human-made technologies. Could this same methodology (i.e., the cost of alternative technology) be applied consistently to the valuation of biodiversity in a kind of science fiction Jurassic Park framework? For biodiversity, money valuation has taken a completely different track, namely the small sums exchanged in some 'bioprospecting' contracts, or fictitious subjective money values in terms of 'willingness to pay' for conservation projects, i.e., the so-called contingent valuation method.

For instance, how to count the service that nature provided us by concentrating minerals which we disperse? ('Exergy' costs have been calculated by industrial ecologists, but the technology for creating mineral deposits does not exist). Therefore, the figures obtained for the money values of environmental services provided free by nature are incongruous. They are useful, however, in stimulating the debate on how 'to take nature into account'.

Ecological economics rests on a foundation of 'weak comparability of values' (O'Neill, 1993; Martinez-Alier et al., 1998). One simple example: let us assume that a new large garbage dump must be built near a city, and that there are three possible locations, A, B, and C, one of which will be sacrificed. In our example, the three different locations are compared under only three different types of value: value as habitat, value as landscape, and economic (monetary) value. Location A is a most valuable publicly owned wetland (valuable as habitat or ecosystem because of its richness of species) but a monotonous landscape, much visited by bird-watchers (and, as such, of some economic value according to the 'travel cost method'). Location B is an old agricultural area of beautiful derelict orchards and ancient manor houses, which ranks first as landscape, but only third as rent-producing, and second as ecosystem or habitat. Location C produces much rent as industrial and urban land, and therefore ranks first in economic value, but ranks only third as an ecosystem or habitat, and comes second as landscape (because of its historical qualities). Which location should be sacrificed? Should and could all values be reduced to a supervalue, so as to achieve strong comparability, and even strong commensurability (cardinal measurement)? In the example, the economic values (in actual or fictitious markets) of all three locations have been taken into account, but there is no supervalue (economic or otherwise such as for instance net energy production by which the wetland would presumably come out on top). Certainly, the present rankings could be reconsidered. Thus, the landscape value of A could be upgraded, and its economic value (as also that of B) could also be increased by contingent valuation. Giving more weight to some criteria than to others, or 'veto thresholds' for some criteria such as the 'endangered species' provision in American legislation, or the introduction of more locations or more criteria, would help us to escape from the deadlock. The point is to show the meaning of 'weak comparability of values'. The decision-making process need not be irrational (by lottery, for instance).

In contrast to such multicriteria approach, in CBA the projects to be evaluated are all valued in the same numeraire (present value in money terms of costs and benefits, including monetarized externalities and environmental amenities).

In microeconomics, there is strong comparability of values, and indeed commensurability, when externalities are internalized into the price system, as in the definition of a Pigouvian tax as the economic value of the externality at optimum pollution level. In macroeconomics, El Serafy's early and influential proposal to 'green' the GDP (in Costanza, 1991) – the results of which will depend on the chosen rate of interest – implied commensurability in money terms. According to El Serafy, not all receipts from the sale of exhaustible resources ('natural capital') should be included in GDP, only one part should be included, 'true' income, and the rest should be counted as 'decapitalization' or the 'user cost' of such 'natural capital', which should be invested at compound interest over the period until the resource is exhausted (as in the Norwegian Oil Fund), so as to allow the country to live at the same standard of living even when running out of the resources. How such a fund can continue to give income if the world runs out of oil is something of a mystery. The proposal, related to Hotelling's rule in resource

microeconomics, is aimed at correcting the macroeconomic accounts. It is based on a notion of 'weak' sustainability only that allows the equivalent substitution of financial or manufactured capital for so-called natural capital–implying therefore a common unit of measurement, i.e., money value – while 'strong' sustainability refers to the maintenance of physical natural resources and services.

The so-called Environmental Kuznets Curve, an inverted U-curve, relates income and some environmental impacts. It has been much debated in ecological economics. For instance, in urban situations, as incomes grow sulfur dioxide emissions first increase and then decrease while carbon dioxide emissions and domestic waste increase with incomes. If something improves and something deteriorates, one reaction from the conventional economist might be to put weights or prices on such effects, in the pursuit of commensurability. However, the uncertainty and complexity of such situations (sulfur dioxide may counteract the greenhouse effect on temperature), and the fact that the price of externalities would depend on the outcome of ecological distribution conflicts, implies that the economists' accounts would be convincing only for the believers of the same school.

When the pattern of use of environmental resources and services and the burdens of pollution are shown to depend on changing social structures and on power and income distribution, then we enter the field of political ecology that studies ecological distribution conflicts. Economic growth leads to increased environmental impacts and conflicts (often outside the market sphere). The response is the growth of a global environmental justice movement (Guha and Martinez-Alier, 1997; Martinez-Alier, 2002). Examples abound of the failure of the price system to indicate such environmental impacts, or (in K.W. Kapp's terms) examples abound of cost-shifting successes. Thus the pattern of prices in the economy would be different without the free access to carbon sinks. Should restrictions be imposed on the 'ecological footprint' of rich economies or on the Human Appropriation of Net Primary Production (HANPP, see below)? Free use of sinks was modeled in a neo-Ricardian or Sraffian framework by Perrings (1987) and O'Connor (1993) showing how the pattern of prices in the economy would be different assuming different outcomes for ecological distribution conflicts.

Related to economic valuation, some remarks are still needed on the discount rate. Economists explain discounting of the future by subjective 'time-preference', or because economic growth per capita caused by today's investments, will make the marginal utility of consumption lower for our descendants than it is for us today. We discount the future because we assume that the future will be more prosperous, and therefore we destroy more exhaustible resources today and we pollute more than otherwise would be the case, thereby undermining future prosperity. This has been called the 'optimist paradox'.

Even accepting the (Ramsey) argument that discounting arises from the productivity of capital, but taking also into account that such 'productivity' is a mixture of true increases in production and of environmental destruction, then the discount factor should be the per capita rate of sustainable economic growth, subtracting therefore the destruction of environmental resources and services and the negative effects of pollution. Now, in order to determine the present economic value of such future effects caused by economic growth (loss of biodiversity, filling up of carbon sinks, production of radioactive waste, etc.), we need not only to put money figures on them (as discussed above), we need also a discount rate. Which?

The current debate on valuation in an intergenerational context goes back to the 'socialist calculation debate' started by Otto Neurath and Ludwig von Mises in Vienna in the early 1920s. Otto Neurath (1882–1945) favored a *Naturalrechnung*, accounting in physical terms, while Von Mises wrote that without prices there could not be a rational economy. Max Weber agreed with Von Mises. Otto Neurath disagreed, and asked how should we decide whether to use more coal now and less human labor, or keep coal for the future and use now more human labor. In today's terms, should we use more fossil fuels now, enjoy economic growth and produce more GHG, rely on technical change and invest in new renewable technologies and geoengineering, or should we go into a steady-state economy after a period of slight degrowth in the rich economies? Collectively, these are technical–ethical questions, they are not decisions that real or fictitious market prices can solve. We cannot enter into market-like negotiations with future generation of humans (or with other species); the methodological individualism of orthodox economic theory breaks down here. Nevertheless, instead of engaging with such arguments, Hayek (1952) in *The Counter-Revolution of Science*, pursuing his 30-year-old disagreement with Neurath, lumped him and other authors (Soddy, Geddes, Mumford) who supported physical accounting into the category of 'social engineers', would-be dictators.

Property Rights and Resource Management

Many years later, one article by Vatn and Bromley (1994) titled *Choices without prices without apologies* explained why money valuation is only optional. Choices depend on socially molded preferences that depend on institutions, that is, the social rules and norms. As Veblen famously put it, the individual consumption of the rich is guided by the social rule of showing off. Bromley and Vatn are institutionalist economists, in Veblen's and Kapp's tradition (while Kapp himself was influenced by Otto Neurath's economics). They see economic behavior not as being determined by inscrutable individual preferences but as influenced and explained by social rules and norms. Institutions articulate a diversity of values (Vatn, 2005).

In this context, Coase's approach to the internalization of negative externalities or positive environmental services into the price system relies on market transactions between partners. So, if an agent (a peasant community, a factory) pollutes the water in a river, the downstream aggrieved agents may get together either to ask for an indemnity equivalent to the damage suffered or to bribe the polluters to stop the pollution, depending on the property rights on the river. This might work without need for government intervention. However, getting the downstream people together to start a court case implies

'transaction costs' (lawyers' fees, time for meetings) that prevent the simple market solution from operating, as Coase himself emphasized. Moreover, when those being polluted are future generations and other species, the market solution does not operate. Regulation (physical norms and fines) or Pigouvian taxation are preferable.

Regarding the empirical study of a very popular policy instrument such as Payment for Environmental Services (PES), one main contribution from ecological economists has been to criticize the simple Coasean, market approach, and introduce complexities related to uncertainty, distributional issues, social embeddedness, and power relations, acknowledging the variety of contexts and institutional settings in which PES operate (Muradian et al., 2010).

The institutionalist perspective (economic actions are explained by social rules more than by inscrutable individual preferences) is very relevant for the study of the relation between property rights or property regimes and the management of natural resources. We go back here to the much quoted article by Garrett Hardin (1968), *The Tragedy of the Commons*, which should have been titled 'the tragedy of open access'. Hardin attended the inaugural conference of the ISEE in Washington, DC, and he had a chapter in the seminal book edited by Costanza (1991). One paragraph in Hardin's article starts like this: "Picture a pasture open to all…", and describes how a tragedy of overgrazing will occur because individuals would put more and more sheep or cows on the pasture provided that the marginal benefit (a few liters of milk, a few pounds of wool, some sacks full of dung) would be larger, individually, than the private marginal cost, disregarding the collective marginal costs in terms of soil degradation.

To the old liberal critique of 'common' property ('the magic of private property (and enclosures) would turn sand into gold' had written Arthur Young) was now added a trendy environmental critique, the Tragedy of the Commons. However, was Hardin not aware of the rules that in the past (brought from England to New England) presumably regulated the amount of horses or cows that a citizen could put to pasture in the Boston Commons? Or in any other commons in the Americas, whether a Mexican ejido or a New Mexican common pasture? Why was the confusion between 'commons' and 'open access' not spotted by the reviewers of Hardin's article in *Science*? There were many well-regulated communal systems of management for forests, coastal fisheries, or irrigation water, as Bromley and others soon retorted and as Elinor Ostrom was to study in detail (Ostrom, 1990).

Hardin's 1968 article mistook commons for open access. It preached privatization (or state property) against the misnamed 'commons'. It took some time until the confusion was cleared up, provoking much research on the functioning of common property regimes, and also on the relations between forms of property and resource management. There are certainly open-access resources, for instance some fisheries in the open seas. The atmosphere was also treated as being in open access to dump polluting substances such as chlorofluorocarbons that damage the ozone layer until an international treaty banned this practice. The atmosphere is still a dumping ground in open access as regards GHG. Other examples abound. But apart from open access (which should be avoided), there were other forms of property.

- The true commons
- Private property
- State and municipal property

Some scholars did research on the trend to turn natural resources held in common and subject to traditional management rules (like coastal mangroves and fisheries in India or Latin America) into *de facto* private property, e.g., for growing shrimp or for fishing for export. This was described not only as a social but also an environmental 'tragedy of enclosures'.

Compared to open access, private property is in principle more conducive to conservation because the costs of today's actions will be felt by the owner or his immediate kin. This was discussed in resource economics at least since Faustmann's rule (1849). The private owner of a forest (or rather, of a tree plantation) will decide to cut the trees not as soon as possible, but when the rate of growth of the trees (net of harvesting costs and multiplied by the market price of wood) falls below the rate of interest in the bank plus the rent to be obtained from the land, now empty off trees (potentially used for crops or pastures while the new stand of plantation trees is starting to grow again). Notice here that a high interest rate (or discount rate) will lead to cutting the trees very soon, while payment for ecosystems, products, or services (like hunting rights, mushroom collection, recreation under the trees, carbon capture) would slow down the rotation period and could even persuade the owner not to cut the trees at all and eventually turn back the plantation into a true forest.

In the case not of trees in a plantation but of extraction of mineral ores or fossil fuels, private property linked to the profit motive is certainly not conducive to conservation, nor to the avoidance of negative environmental impacts after the exhaustion of the resource such as acid drainage from mines. An oligopoly such as Organization of Petroleum Exporting Countries slows down oil extraction because of economic and not environmental objectives. New institutions, that is, rules articulating new values (for instance, civil or criminal legislation on socioenvironmental liabilities) would perhaps modify the behavior of the extractive industries.

Social Metabolism and Indexes of (Un)Sustainability

Because of the shortcomings of money valuation, ecological economists favor physical indicators and indices in order to judge the overall impact of the human economy on the environment. Therefore, we leave here aside monetary corrections to GNP, such as El Serafy's (see above), or Hueting's (in Costanza, 1991), which calculated the economic costs of adjusting the economy to socially negotiated norms or standards of pollution and resource extraction, in a 'cost-effectiveness' approach (by 'cost effectiveness', it is meant the analysis of the cheapest way, in money terms, in order to adjust the economy to such physical norms or standards). We also leave aside the ISEW (see above) whose end result is a figure in money terms commensurate with GDP though often showing quite a different trend.

According to Georgescu-Roegen (1971), economics should see the economy as an open system (and not as a self-sustaining system, a 'merry-go-round' between consumer and

producers as in the textbooks). Economics should study the 'metabolic flows' in the economy. This is today linked to two research schools. The first one centers on Marina Fischer-Kowalski's collaborators at the Institute of Social Ecology in Vienna, drawing on work by Robert Ayres, R.P. Sieferle, and other authors. This group has developed methods for the study of the social metabolism, listed below.

The second school would be Marxist ecological economics. It has much less influence. It claims with reason that Marx already wrote in the 1860s that the capitalist economy was causing a 'metabolic rift' (Foster, 1999) between humans and nature. Marx took the work metabolism (*Stoffwechsel*) from Moleschott and Liebig, pointing to the export of nutrients in the soil by commercial agriculture. Capitalism not only exploited workers but also exploited the soil. The soil was no longer a 'fund' able to supply crops continuously; it became an exhaustible stock in terms of its fertility and texture. Marx quoted Liebig who feared the day when guano imports would diminish. Marx, as Liebig, hoped for factory-made chemical fertilizers (in a sort of 'weak sustainability' approach) to escape the Malthusian trap of 'diminishing returns'. Despite such intellectual traces, a Marxist ecological economics or environmental history has not existed until the end of the twentieth century from Altvater (2007), Bellamy Foster, Hornborg (in his theory of ecologically unequal trade, Hornborg, 1998), and O'Connor's 'second contradiction' (O'Connor, 1988).

Going back to the first school, here is a summary of today's methods for the study of social metabolism trying to ascertain the trends in the use of materials and energy in the economy. They allow concrete answers to questions such as, "is the economy dematerializing in absolute terms, or only relatively to GDP growth", "has the human appropriation of biomass increased as fast as population in the last 100 years", and "is the energy cost of obtaining energy increasing?"

- Calculations of material flows (in tons), often divided into biomass, building materials, mineral ores, fossil fuels, at national or regional levels. Therefore, one can test the hypothesis of 'dematerialization' of production or consumption, and one can do calculations of physical trade balance supporting the arguments on ecologically unequal trade (Pérez-Rincón, 2006; Weisz et al., 2006; Russi et al., 2008).
- Calculation of energy flows at national or regional levels including historically changing ratios of exosomatic energy use/endosomatic energy use (Giampietro et al., 2013), calculations of the EROI (Hall et al., 1986). EROI calculations show whether there is a trend toward an increasing energy-cost of obtaining energy. Some anthropologists analyzed the basic economics of human society as a flow of energy (e.g., Roy Rappaport's *Pigs for the Ancestors*, 1968). Engels in 1882 discussed this topic with Marx sadly denying the relevance of Podolinsky's agricultural energetics for Marxian economics. Max Weber in 1909 had criticized Wilhelm Ostwald's interpretation of economic history in terms of (1) an increased use of energy, (2) an increased efficiency in the use of energy, because economic decisions on new industrial processes or new products were based on prices, entrepreneurs did not pay attention to energy accounts per se. Max Weber did not yet question energy prices from the environmental viewpoint as we would today. In the 1970s David Pimentel (Pimentel et al., 1973) showed the decreasing energy efficiency in maize cultivation in the United Sates. A new field was opened up by such studies on the efficiency in the use of energy in different sectors of the economy, including the energy sector itself.
- Calculations of 'virtual water' in import or in exports (e.g., wheat, soybeans, meat, ethanol, cellulose) at regional or international levels, i.e., the water 'dissipated' in growing crops, pastures, timber. It was argued by Tony Allan in the 1990s that water disputes in the Middle East were mitigated by importing food. Hoekstra and Chapagain (2007) have calculated water footprints of nations, and there is research on the unpaid water transfers embodied in trade in commodities.
- Calculations of HANPP (including the 'embodied HANPP', which is relevant for trade statistics) (Vitousek et al., 1986; Krausmann et al., 2013). The driving idea is that the larger the amount of potential biomass production appropriated by humans in a given territory, the less biomass is available for other (nondomestic) species, and therefore the more likely the loss of biodiversity. The proportion of NPP appropriated by humans is increasing because of increasing demands of land for urbanization and infrastructures, for growing feedstuffs and agrofuels, for growing timber.

All the indexes mentioned above are measured in different units and might show different trends, although there are also some rules of congruence among them. There are no cases of rapid GDP growth and persistent degrowth in material flows (particularly when trade effects are taken into account). But it might happen that increasing fossil fuel inputs into agriculture will increase yields and slow down the increase in the HANPP. How should a situation be judged in which, for instance, an index such as material flows slightly improves while HANPP deteriorates, EROI decreases, GDP grows, infant mortality decreases, and self-reported life satisfaction is stable? Notice that the human development index regularly published by United Nations Development Program adds up economic and social indicators into a single number but it does not include environmental impacts at all. Commensurability would imply reducing such values to an encompassing supervalue but this is not necessary in order to reach reasonable integrated assessments by macroeconomic multicriteria evaluation (Shmelev, 2012).

There is one composite physical index of (un)sustainability that was born within ecological economics and has had great success in public opinion: the Ecological Footprint, first presented by Bill Rees (an ecologist turned urban planner) around 1991. Which is the environmental load of the economy, in terms of space? H.T. Odum had posed the question, and later authors developed some answers. Rather than asking what maximum population a particular region or a country can support sustainably, the question becomes: how large an area of productive land is needed (as source and sink) in order to sustain a given population indefinitely, at its current standard of living and with current technologies? The Ecological Footprint is the inverse of the carrying capacity (see below). Computations, not only for cities or metropolitan regions (whose 'ecological footprint' is hundreds of times larger than

their own territories) but also for countries, show that some densely populated European countries or Japan and Korea (assuming per capita eco-footprints of 2 or 3 ha) occupy eco-spaces 10 times larger than their own territories (Wackernagel and Rees, 1995). The Ecological Footprint is rightly criticized because it adds up actual land use (say, 1 ha per person for food, feed, and timber) and notional or 'virtual' land use (say, another hectare) for the absorption by photosynthesis of the carbon dioxide produced by burning fossil fuels. The results are sometimes expressed in terms of how many real plus virtual planets humankind is using. Already we are using one and a half. But this depends on the amount of land that is left for other species. If the HANPP would be reduced by half for that purpose, then the Ecological Footprint of humans in terms of extra planetary needs would be even more alarming. Despite these and other critiques, the Ecological Footprint has enjoyed great success possibly because a spatial representation of environmental impact is easily understood.

On Population

Ecological economists emphasize both the pressure of population and the pressure of production (and consumption) on resources. How large is humankind's ecological footprint? Has humankind exceeded 'carrying capacity'? This is defined in ecology as the maximum population of a given species, such as frogs in a lake, which can be supported sustainably in a given territory without spoiling its resource base. However, the large differences internal to the human species in the exosomatic use of energy and materials, mean that the first question is, maximum population at which level of consumption? Second, human technologies change at a quick pace. Already Boserup's thesis (1965) of endogenous technical change according to which preindustrial agricultural systems had intensified in response to increases in population density, tried to turn the tables on the Malthusian argument. Third, the territories occupied by humans are not 'given', other species are pushed into corners or into oblivion (as the index HANPP implies), and, internal to the human species, territoriality is politically constructed through state borders. Fourth, international trade (similar to horizontal transport in ecology, but which humans can regulate consciously) may imply 'ecologically unequal exchange', though if one territory lacks a very necessary item which is abundantly present in another territory, Liebig's law of the minimum would recommend exchange. Then, the joint carrying capacity would be larger than the sum of the carrying capacities of all autarchic territories.

Because of the shortcomings of 'carrying capacity' as an index of (un)sustainability for humans, and because of Barry Commoner's arguments against Paul Ehrlich's fixation on population growth (Ehrlich, 1968) allegedly forgetting that overconsumption was the main environmental threat, the formula I = P.A.T was proposed by Ehrlich himself, where I is environmental impact, P is population, A is affluence per capita, and T stands for the environmental effects of technology. Efforts are being made to operationalize I = P.A.T. True, population remains one important variable. True also, the demographic transitions are not mere automatic responses to urbanization and education, and their timing does not depend only on inheritance patterns and family forms. Human demography is anticipatory and self-conscious. Though it also follows Verhulst's curve, it is different from the ecology of a population of frogs in a lake.

There have been three different varieties of Malthusianism. First, Malthus' own view in 1798 that human populations would grow exponentially unless checked by war and pestilence, or by the unlikely restraint of chastity and late marriages. Food would grow less than proportionately to the growth of the labor input, because of decreasing returns. Hence, subsistence crises.

Then there was the Neo-Malthusianism of 1900, with radical activists such as Emma Goldman, Paul Robin (Ronsin, 1980). Human populations could regulate their own growth through contraception. Women's freedom was required for this, and it was desirable for its own sake. This was a feminist Neo-Malthusianism, insisting on what is called today 'reproductive rights'. Abortion and vasectomies should not be criminalized. 'Conscious procreation' was required in order to prevent low wages and pressure on natural resources but the main cause of poverty was social inequality. This was a successful bottom-up movement only in some parts of the world, particularly in Europe and America against States (which wanted more soldiers) and against the Catholic Church.

There is finally top-down Neo-Malthusianism after 1970, reaching extremes like Hardin's 'lifeboat ethics' (Hardin, 1974) against freedom of migration with racist overtones. This top-down doctrine and practice is sponsored by international organizations and some governments. Population growth is seen as one main cause of poverty and environmental degradation. Therefore, states must introduce contraceptive methods, even sometimes without the populations' (particularly women's) prior consent.

Ecological economists have been divided into top-down and bottom-up Neo-Malthusians with lack of dialogue between them although they all refuse the doctrines of the anti-Malthusians, who assume that human population growth is no threat to the natural environment, and that it is conducive to desirable economic growth. Ecological economists believe that growth of world population (four times in the twentieth century) is certainly a very major issue. It now seems that population might be stabilized and even go into a slow decline after 2050, at less than 9 billion people. This is welcome. Fertility is going down in many regions and countries. The demographic transition is being completed. This is a good thing, although local depopulation (not only rural, but also urban) may create new social and environmental problems.

Civil Society and Ecological Economics

There is no doubt about the present influence of the main schools of economics on governments and public opinion (perhaps except for Marxism but certainly including Keynesianism, Schumpeterian economics, neoliberal or market fundamentalism, etc.). But one can doubt still whether ecological economics is having any influence at all. Who and where are the nonacademic 'consumers' of ecological economics?

So far, despite the overarching vision of Georgescu-Roegen and his followers, no politician ever quotes in public debate the entropy law and its relevance for the economic process while many discuss the large or little ups and downs of GDP, and the public debt risk ratings. Detroit's municipal default of 2013 seems more relevant to both neoliberal and Keynesian public opinion leaders in rich countries than the world ecological debt. Nevertheless, the critiques of national income accounting by ecological economists and by ecofeminist economists have certainly influenced the sporadic and rather fruitless movements to move 'beyond GDP' by governments and international bodies. It is obvious that many caring activities in families and in society and many services of nature (Waring, 1988), remain outside the market, and therefore are unaccounted for although they are essential for social reproduction and human well-being. This is commonly accepted. Further, a civil society group in the United States is promoting the steady-state economy. Its motto is: "Growth, especially in wealthy nations, is already causing more problems than it solves." It has over 10 000 members.

Meanwhile, the economic valuation and payment for ecosystem services has become a growth industry in Ministries of the Environment and Forests, worldwide. Also, trends of the decarbonization of the economy and also of its material intensity are mentioned in political debates in some countries. But there is an enormous gulf between the critiques from ecological economics and current government and business practices. Business circles are, like governments, eager consumers of economic doctrines but they ignore ecological economics. At most, the debates on the environmental liabilities from private or public companies, also known as 'the social costs of private enterprise' (Kapp, 1950), have given rise to so far aimless discussion of how to take the environmental damages into the actual accounts beyond 'greenwashing' corporate social responsibility exercises (Sukhdev, 2012). Moreover, some legal avenues to claim environmental liabilities from companies (such as the Alien Tort Claims Act legislation in the United States) are closing down.

Other notions from ecological economics, such as ecologically unequal trade, have been taken up by environmental groups from the South, especially by 'postextractivist' groups in Latin America. For instance, the metabolism of soybean production (loss of soil nutrients and 'virtual' water), and the damage from glyphosate spraying in Monsanto genetically modified crops, is a growing issue in the politics of Argentina (Pengue, 2005).

Via Campesina is an international network of peasant and landless workers' organizations. Drawing on studies of the energetics of the modern food systems, it claims that traditional peasant agriculture cools down the Earth. Vice versa, concepts like the ecological debt or carbon debt have progressed from activist circles to the speeches of ministers or even heads of state from some countries in the South, and then to academic journals (Srinivasan et al., 2008). Similarly, concepts like Degrowth get support from social movements (the *Décroissance* movements in Europe), easily connecting to Jackson's and Victor's academic ecological macroeconomics without growth. The European Ecological Economics Society (a very active branch of the ISEE) supports the activist and academic conferences on Degrowth (not without internal debate), a position very unlikely to be taken and for good reasons by the Indian Ecological Economics Society. The reception of and contributions to ecological economics by civil society organizations have been researched by Healy et al. (2012).

For instance, on a new issue like geoengineering (combating climate change through ocean iron fertilization, sulfate aerosol spraying, etc.), although the ISEE will not take a political position, already a well-known Australian ecological economist, Clive Hamilton (2013), has provided something like the ecological economist's party line (which is similar to that anticipated by Pat Mooney of the civil society organization ETC), showing that geoengineering is fraught with new dangers, that the precautionary principle should be applied, that the debate should be opened up as in the 'postnormal science' approach (Funtowicz and Ravetz, 1994), and that climate change mitigation in the form of reducing emissions is preferable to such doubtful experiments with uncertain consequences. Ecological economists will differ among themselves, however, on the measurement of costs of climate change mitigation, and even on the proper units of account of such costs.

The Society for Ecological Economics

Could the ISEE (born in the late 1980s) be seen in future as remotely similar in influence (though very different in intention) to the Mount Pelerin society founded by Hayek in 1947 to defend the market economy and Karl Popper's 'open society' against Marxist doctrines and Keynesian social-democratic planning? Should the ISEE have a political objective? Is the pluralism in ecological economics undermining such a prospect, or rather, is it the radicalism of ecological economics preventing or delaying its social acceptance? Should we relent a bit and accept 'weak sustainability' and the promises of ecological modernization, or should we denounce UNEP's 'green growth' of 2013 as an oxymoron even more blatant than Brundtland's 'sustainable development' of 1987? In fact, should 'we' (ecological economists) have any collective position at all?

The ISEE has lived up to its promise of promoting a transdisciplinary field at the intersection of ecology and economics. Both economists and ecologists coming from different schools have been active in the field. This article has briefly explained the origins of ecological economics going back to the late nineteenth century. Therefore, it is not true that "ecological economics is simply what ecological economists do". They do many different things but within a common tradition which is not clearly delimited because it is at the interface of related fields.

While the journal *Ecological Economics* and the biennial conferences are the main focus of activities of the ISEE, there are active regional societies in the United States, Europe, India, Latin America, and Russia. The European Society for Ecological Economics edits also another journal, *Environmental Policy and Governance*. The Latin American ecological economists publish the journal *Revibec*. Well-known ISEE members have edited related journals: Charles Perrings, *Environment and Development*; Clive Spash, *Environmental Values*; Robert Costanza, *Solutions*; and Jeroen van den Bergh, *Environmental Innovation and Societal Transitions*. The Indian Society (INSEE) regularly publishes

proceedings of well-attended conferences. Her past-president, Kanchan Chopra, gave her name to a famous committee mandated in 2002 by the Supreme Court, giving the methodology for calculating Net Present Values of nonmarket forest products and services sacrificed by mining or hydroelectric projects.

Among all this variety, there is a common thread. A sample of first university degrees and main scientific interests of the (older) ecological economists can be constructed by listing the names of the ISEE presidents since 1989, as follows.

- Robert Costanza, systems ecology, architecture, energy in the economy, ecosystem services
- R.B. Norgaard, economist, postdevelopment studies, coevolution, biodiversity conservation
- John Proops, physicist, energy in the economy, capital theory, economic–ecological modeling
- Charles Perrings, economist, development studies, economics of biodiversity
- Joan Martinez-Alier, economist, energy in society, environmental history, political ecology
- Peter May, resource and environmental economist, development, Amazon deforestation
- John Gowdy, economist, economic anthropology, economics of consumption
- Bina Agarwal, economist, development and feminist economics, common property, India
- Marina Fischer-Kowalski, sociologist, industrial ecology, social metabolism, transition societies

This can be complemented by the list of recipients of the ISEE Boulding Award: Herman Daly (economist), Robert Goodland (biologist), A.M. Jansson (ecologist), Robert Costanza (ecologist), C.S. Holling (ecologist), Robert U. Ayres (physicist, industrial ecologist), Partha Dasgupta (economist), K.G. Mäler (economist), R.B. Norgaard (economist), Charles Perrings (economist), Manfred Max-Neef (economist), Ignacy Sachs (economist), Joan Martinez-Alier (economist), Bill Rees (ecologist), and Mathis Wackernagel (ecologist), roughly divided by half into ecologists (biologists, physicists) and economists according to their original training. Their names have often appeared in the present article.

Outlook

Ecological economics is then a transdisciplinary field born in the late 1980s, founded by ecologists and by dissident economists, which studies new topics and applies methods such as:

- New indicators and indices of (un)sustainability of the economy;
- Ecological macroeconomics without growth, the debate between 'weak' and 'strong' notions of sustainability;
- The application of ecological notions of carrying capacity and resilience to human ecosystems;
- The valuation and payment for environmental services, monetary valuation of externalities but also the discussion on incommensurability of values;
- Risk assessment, uncertainty, complexity, and 'postnormal' science; integrated environmental assessment, including building of scenarios, dynamic modeling, participatory multicriteria methods of decision making;
- The allocation of property rights and its relation to natural resource management, old and new communal institutions for environmental management;
- Environmental causes and consequences of technological change, relations between ecological economics and evolutionary economics;
- Theories of consumption (needs, satisfactors), as they relate to environmental impacts;
- Relations to industrial ecology, applications to business administration, corporate liability and accountability;
- Relations to fields such as feminist economics; environmental and economic history; environmental ethics; political ecology, urban planning, peasant studies;
- Environmental public policies, instruments of environmental policy often centered on the 'precautionary principle' (or 'safe minimum standards', as introduced by Ciriacy-Wantrup).

Abstract

Researchers commit an 'ecological fallacy' when they offer mistaken inferences about individual-level relationships using associations observed only in aggregate data. This mistaken inference practice is labeled a fallacy because it is based on the false assumption that relationships that hold at one level of aggregation must also hold at another level of aggregation. Because individual-level data often are unavailable, researchers are at risk of succumbing to ecological fallacies in virtually all the social and behavioral sciences. In this article, the methods of Firebaugh and King are presented as attempts to avoid fallacies and improve interpretations of available aggregate data.

Researchers are said to commit the 'ecological fallacy' when they make untested inferences about individual-level relationships from aggregate data. This practice is called a fallacy because it is based on the problematic assumption that relationships that hold at one level of aggregation also hold at another level of aggregation. Researchers are subject to the ecological fallacy in virtually all the social and behavioral sciences, from history (where individual-level data often are unavailable) to criminology (where, for example, a positive relationship between poverty rate and crime rate across cities might be interpreted as evidence that poor people commit more crime) to epidemiology (where preliminary studies might correlate cancer rates across regions with other regional characteristics to decide what sorts of expensive individual-level data to collect).

This article cites examples of the ecological fallacy, explains why inference across levels of aggregation is sometimes unavoidable in social science research, and overviews solutions that have been proposed for alleviating the problem. Because individual-level data are not available for studying many issues of concern to social and behavioral scientists, the article emphasizes the theoretical conditions under which individual-level and aggregate-level relationships are the same.

An Example

One important contemporary example involves the relationship between race and voting behavior in the United States. The assumption is that voters have a propensity to vote for someone of their own race: whites are more likely to vote for a white candidate, blacks for a black candidate, and so on. If there is a propensity for intra-racial voting, candidates are handicapped in political districts where their race is different from that of the majority of the voters. A probable outcome is that members of minority races will be underrepresented in governing bodies because of their minority status in almost all political districts. One proposed solution is to use race as an explicit criterion for determining political districts, with the goal of drawing district boundaries in such a way that blacks and other minorities are in the majority in some of the election districts.

This issue poses the classic ecological fallacy problem for researchers because the use of the secret ballot rules out the best source of data on how individuals actually voted. To make sound policy decisions about the use of race as a criterion for drawing up political districts, policy makers should know the strength of intra-race vote propensity, yet individual-level data typically are not available for estimating that propensity. Voting data come in aggregated form, by precincts. Hence researchers often must rely on correlations for voting data aggregated to the precinct level. In an election pitting a white candidate against a black candidate, for example, researchers might attempt to use the correlation between a precinct's percentage of white voters and the percentage of votes for the white candidate to draw inferences about the propensity of whites to vote for white candidates.

Those inferences are problematic because relationships at the precinct level need not equal relationships at the individual level. Even the direction of the relationship can be different for individuals and aggregates. The 1968 US Presidential election provides a real-world example. In that election, George Wallace, a third-party candidate who was known primarily for his segregationist position as Governor of Alabama, captured about 10% of the national vote. What is relevant here is that in the South he tended to receive a higher percentage of the vote in congressional districts with higher percentages of blacks (the correlation across districts in the South was $r = 0.55$ (Firebaugh, 1978)). Because no one believes that blacks were more inclined than other racial groups to vote for George Wallace, this is a compelling example of the danger of using aggregate data to draw inferences about the behavior of individuals.

Why was there a positive correlation between percent black and vote for Wallace in the 1968 election? The answer is that whites in heavily black districts were more likely to vote for Wallace than were whites in districts with fewer blacks. In other words, in this election the effect of one's race on one's voting behavior was affected by one's racial context – an example of a contextual effect (*see* Contextual Studies: Methodology). Subsequently, this article shows that relationships differ at the

individual and aggregate levels when such contextual effects are present.

The Impact of the Ecological Fallacy on Research Practices

Although the term ecological fallacy is most often associated with W.S. Robinson, Robinson does not use the term in his classic 1950 article. Instead he uses the term 'ecological correlation,' and he states that his analysis "provides a definite answer as to whether ecological correlations can validly be used as substitutes for individual correlations. They cannot" (Robinson, 1950: p. 357). Robinson uses illiteracy data from the 1930 US census to show the discrepancy between ecological correlations and individual correlations. The correlation between percent black and percent illiterate is $r = 0.77$ across States and $r = 0.95$ across nine larger geographic divisions of the United States. The size of those ecological correlations stands in stark contrast to the size of the individual-level relationship between race (black vs others) and illiteracy ($r = 0.20$). As a second example, Robinson notes that the ecological correlation of percent foreign-born and percent illiterate across States is large and negative ($r = -0.53$), suggesting that the foreign-born are substantially less likely to be illiterate. Yet the foreign-born actually are more likely to be illiterate, as shown by the positive correlation at the individual level ($r = 0.12$).

While Robinson focused on the danger of using aggregate data to draw conclusions about the behavior of individual people, the ecological fallacy problem in fact applies to inferences across levels of aggregation in general. Individuals need not be people. The terms individual level and aggregate level as used here refer to relative levels of aggregation. To illustrate, the term 'individual' could refer to a single church congregation within a population of congregations. The ecological fallacy problem would arise if a researcher tried to use data on racial diversity and attendance growth rates across church denominations (collections of congregations) to draw conclusions about the effect of racial diversity on local church growth. Because parishioners attend a local congregation, it is racial diversity at the local level, not at the denomination level, which is the natural focus here. One could of course survey local congregations in this instance, but the survey would ask questions about a collective (a congregation) rather than about a person.

It would be difficult to overstate the impact Robinson's article has had on social science research during the second half of the twentieth century. The use of ecological correlations to study individual-level relationships had been commonplace before Robinson's article, and the article sharply curtailed that practice. The article also served to motivate the development of survey research. If aggregate data are not adequate to study individuals, then social scientists need data on individuals. One efficient way to gather data on individuals is to ask them questions. Hence, in this way Robinson's message about the need for individual-level data to study individuals no doubt played a role in the amassing of the large survey data sets that have become standard fare in social science research in the twenty-first century.

It is sometimes difficult or impossible to collect survey data to overcome the ecological fallacy problem, however, for two main reasons. First, individuals might be hard to reach. The extreme case of this occurs in historical research, where the pertinent individuals are dead. For this reason, historical research is especially plagued by the ecological fallacy problem (geography is another discipline especially affected, since geographic research is often based on spatial units). Aggregate data often are the only data available to historians, and it is not possible to go back in time to collect data to determine who voted for the Nazis, for example. Second, individuals might be reachable, but the needed information is sensitive. To protect the privacy of individuals, government agencies in some instances aggregate individual-level data before releasing the data to researchers. But aggregation in turn creates the risk that researchers using the aggregate data might commit the ecological fallacy.

Mitigating the Ecological Fallacy Problem

No expert disputes Robinson's claim that aggregate-level relationships very often differ markedly from individual-level relationships, but a very active literature since Robinson takes issue with his strict prohibition against the use of aggregate data to study individual-level relationships. Necessity motivates this literature; given the unavailability of individual-level data for many issues of interest in the social and behavioral sciences, the Robinson prohibition would rule out research in some areas of compelling interest, as illustrated by the earlier example of race and voting behavior.

Writing shortly after the Robinson broadside, Goodman (1953, 1959) observed that aggregation tends to affect correlation coefficients (r) more than it does regression slopes and that, under certain statistical conditions, aggregate-level and individual-level slopes are the same. The challenge has been to translate Goodman's statistical conditions into broadly applicable substantive terms that researchers can use. That challenge has resulted in extensive literature on the ecological fallacy in sociology, geography, economics, political science, and history. One prominent approach seeks to spell out the conditions under which aggregate-level coefficients provide unbiased estimates of individual-level parameters. A second approach seeks to use a method-of-bounds to derive estimates of individual-level effects. This article concludes by briefly overviewing the two approaches.

Equivalence Conditions for Aggregate-level and Individual-level Parameters

Since the Robinson and Goodman articles in the 1950s, much of the methodological work on the ecological fallacy has been devoted to spelling out the conditions under which aggregate-level coefficients provide unbiased estimates of individual-level relationships. Following Goodman's lead, this work focuses on regression slopes, since the bias tends to be smaller for slopes than for correlation coefficients. Hannan and Burstein (1974) consider the effects of the variable by which the data are grouped (e.g., precincts, schools, and States). For the bivariate case, they show that aggregate data yield unbiased estimates of individual-level relationships when the grouping variable is either (1) uncorrelated with the independent variable or

(2) uncorrelated with the dependent variable, with the independent variable controlled for. Applied to the example of race and voting behavior, the precinct-level data provide unbiased estimates of individual-level voting behavior when precinct is unrelated to race, or precinct is unrelated to voting behavior, controlling for race. The first condition is improbable, since neighborhoods in the United States tend to be highly segregated by race. The second condition (voting behavior is unrelated to precinct, race controlled for) means that one's propensity to vote for a same-race candidate is unaffected by the racial makeup of one's precinct. Thus, whites in majority-black precincts are as likely to vote for the white candidate as whites in majority-white precincts, blacks in majority-white precincts are as likely to vote for the black candidate as blacks in majority-black precincts, and so on. Unless Americans of all races are remarkably oblivious to their social contexts, this assumption is unlikely to hold.

Firebaugh (1978) subsumes the Hannan–Burstein conditions under a single rule. The rule states that the aggregate-level regression slope provides an unbiased estimate of the corresponding individual-level effect of X on Y if and only if aggregated X (denoted $\overline{X}$ since aggregated X is usually a type of mean) is unrelated to Y, controlling for individual-level X. For example, using precinct-level data to estimate the effect of one's race on one's vote will yield a biased estimate of that effect unless the racial context of precincts is unrelated to one's vote. Firebaugh shows that the $\overline{X}$ rule generalizes to the multivariate case where a researcher wants to estimate the effect of more than one independent variable.

Firebaugh's $\overline{X}$ rule suggests one solution to the ecological fallacy problem: eliminate $\overline{X}$ effects. To eliminate X effects, researchers must determine why $\overline{X}$ might have an effect on Y beyond the effect of individual X, and then add variables to try to remove the effect. Using the voting example to illustrate the first step is to ask why it is that the racial composition of one's precinct might be related to one's vote, independent of one's race. The most likely answer is that minorities in largely white precincts differ from minorities in largely nonwhite precincts on a host of factors, *other than race*, that are related to voting characteristics, such as income, education, and home ownership. These nonracial characteristics of the precincts should be entered into the aggregate-level equation as control variables. Here the logic of control is the conventional logic used in nonexperimental analysis: regressors are included (average income in the precinct, average education level, percent homeowners, etc.) in an attempt to use the least-squares method to 'equate' the precincts on those properties (Gelman and Hill, 2007). If the method is successful, the aggregate-level slope for race will reflect the effect of race for voters who live in precincts that are otherwise equivalent – that is, the aggregate-level slope will reflect the effect of race itself on vote.

Bounding Individual-level Parameters

The $\overline{X}$ rule is not a foolproof solution to the ecological fallacy problem since there is no way (with aggregate data only) to test the assumption that $\overline{X}$ effects have been eliminated. Hence, methodologists continue to work on the problem. One line of work gains leverage on the problem by applying the insight that marginal frequencies bound the cell frequencies in a contingency table (Duncan and Davis, 1953). For example, in a precinct where 500 whites and 100 nonwhites collectively cast 450 votes for candidate A, the number of nonwhites voting for candidate A is bounded by 0 and 100 and the number of whites voting for candidate A is bounded by 350 and 450.

A book by King (1997) entitled *A Solution to the Ecological Inference Problem* combines the bounding principle of contingency tables with probabilistic statistical methods to fashion a sequential procedure for estimating individual-level coefficients and their confidence intervals. In essence, the method begins with the deterministic information provided by the bounds for each of the aggregates (e.g., precincts) and then applies likelihood methods to narrow probabilistically within those bounds. A public-domain computer program provides estimates, visual depictions, and diagnostic tests. King's method is the most ambitious attempt to date to provide a general solution to the ecological fallacy problem. Ultimately, the worth of a tool is proven in use, and the most telling test of King's method and its successors will come as researchers apply them (see King et al., 2008 for an example of the method).

Abstract

There is a long tradition, in the social and life sciences, of attempts to infer individual behavior from group behavior. Durkheim's book on suicide is an early example. The 'ecological fallacy' consists of ascribing to individuals the characteristics of groups to which they belong, even though the relevant individuals may not share such characteristics. The issues are discussed in seminal papers by Robinson, Duncan and Davis, and Goodman, which are summarized here. Ecological regression is considered, along with recent work on random-coefficients models. Examples are drawn from epidemiology, voting rights, and survey data.

In nineteenth century Europe, suicide rates were higher in countries that were more heavily Protestant, the inference being that suicide was promoted by the social conditions of Protestantism (Durkheim, 1897); also see Neeleman and Lewis (1999). According to Carroll (1975), death rates from breast cancer are higher in countries where fat is a larger component of the diet, the idea being that fat intake causes breast cancer. These are 'ecological inferences,' that is, inferences about individual behavior drawn from data about aggregates.

To continue with Durkheim, the Protestant countries were different from the Catholic countries in many ways besides religion (the problem of 'confounding'). Moreover, his data do not tie individual suicides to any particular religious faith. Confounding must be dealt with in any observational study. But the second problem – that exposure and response are measured only for aggregates rather than for individuals – is specific to ecological studies. If there is no confounding, the expected difference between effects for groups and effects for individuals is 'aggregation bias'; in general, the difference is partly attributable to confounding and partly to aggregation bias.

The ecological fallacy consists of thinking that relationships observed for groups necessarily hold for individuals: if countries with more Protestants have higher suicide rates, then Protestants must be more likely to commit suicide; if countries with more fat in the diet have higher rates of breast cancer, then women who eat fatty foods must be more likely to get breast cancer. These inferences may be correct, but are only weakly supported by the aggregate data.

Ecological studies in epidemiology yielded important insights for Snow (1855), Finlay (1881), Goldberger (Terris, 1964), and Dean (1938) among others. However, it is all too easy to draw incorrect conclusions from aggregate data. Greenland and Robins (1994) review the issues. For one example, recent studies of individual-level data cast serious doubt on the link between breast cancer and fat intake (Holmes et al., 1999). Another well-known example, on the sources of popular support for the Nazi party pre-war Germany, is discussed by Lohmoller et al. (1985).

Ecological Correlation

Robinson (1950) discusses ecological inference, stressing the difference between ecological correlations and individual correlations. One striking example is the relationship between nativity and literacy. For each of the 48 states in the US of 1930, Robinson computes two numbers: the percentage of the population who are foreign-born, and the percentage who are literate. (The base for each percentage is the number of residents of the state who are 10 or older; data are from the Census of 1930.) The correlation between the 48 pairs of numbers is 0.53. This is an 'ecological' correlation, because the unit of analysis is not an individual person but a group of people – the residents of a state. The ecological correlation suggests a positive association between foreign birth and literacy: the foreign-born are more likely to be literate (in American English) than the native-born. In reality, the association is negative: the correlation computed at the individual level is −0.11. The ecological correlation gives the wrong inference. The sign of the correlation is positive because the foreign-born tend to live in states where the native-born are relatively literate.

The example can be replicated using data from the March 1995 Current Population Survey, restricted to persons age 25 and over. Literacy is not reported, but incomes are. Say that a person has 'high' income if family income in 1994 was $50 000 or more. Figure 1 shows for each of the 50 states the

Figure 1 For each state, the horizontal axis shows the fraction of the population aged 25 and over that is foreign-born; the vertical axis shows the fraction having high incomes. The regression line is also shown.

fraction of persons who are foreign-born, and the fraction of persons who have high incomes. The regression line is shown too. The ecological correlation (across the 50 areas) is 0.52, suggesting that the foreign-born have higher incomes on the whole than the native-born. The truth is the opposite. About 35% of the native-born have high incomes, compared to 28% for the foreign-born. The correlation at the individual level is −0.05. In Figure 1, there is no state where the fraction of foreign-born approaches 1. However, the same sort of reversal can occur even with a full spectrum of x-values. The issue is the disaggregation, not the range of the data.

Ecological Regression

Under certain restrictive assumptions, individual behavior can be inferred from aggregate data using a technique called 'ecological regression.' The unit of analysis in the regression is a group of people, typically defined by geography (as in Figure 1). The technique has been widely used in voting rights litigation in the US. For discussion from various perspectives, see Dogan and Rokkan (1969), Freedman et al. (1991), Grofman and Davidson (1992), Achen and Shively (1995), and Cho (1998).

It may, for instance, be desired to estimate the support for a particular candidate among Hispanics and non-Hispanics. For each precinct in an electoral contest, suppose we know the fraction x of voters who are Hispanic; we also know the fraction y of votes obtained by the candidate of interest. We would not know the fraction of Hispanic voters who voted for the candidate, due to the secrecy of the ballot.

A regression equation can be fitted to the data:

$$y_i = a + bx_i + \varepsilon_i \qquad [1]$$

In eqn. [1], the subscript i indexes precincts; x_i is the fraction of voters in precinct i who are Hispanic; y_i is the fraction of votes cast in that precinct for the candidate of interest. (More exactly, y_i is the number of votes for that candidate, divided by the number of voters.) The precinct-level disturbance terms ε_i would typically be assumed to be independent and identically distributed with mean 0, although this is seldom made explicit.

The parameters a and b in eqn. [1] can be estimated by ordinary least squares; call the estimates $\widehat{a}$ and $\widehat{b}$, respectively. Then $\hat{a}$ would be interpreted as the fraction of non-Hispanic voters who supported the candidate in question: after all, $\hat{a}$ is the height of the regression line at $x = 0$, corresponding to precincts with no Hispanic voters. Likewise, $\widehat{a} + \widehat{b}$ (the height of the regression line at $x = 1$) would be interpreted as the fraction of Hispanic voters who supported the candidate.

The data are available for groups defined by area of residence; the inference is to groups defined by ethnicity. The statistical logic connecting the inference to the data rests on the 'constancy assumption,' that voting preferences within ethnic groups do not systematically depend on the ethnic makeup of the area of the residence (Goodman, 1953, 1959). In Figure 1, the regression equation is $y = 0.29 + 0.56x$, leading to the inference that 30% of the native-born have high incomes, compared to 29% + 56% = 85% of the foreign-born. In reality, as noted above, the percentages are 35 and 28%. The ecological inference is in error, because the constancy assumption fails: the incomes of the native-born increase systematically with fraction of foreign-born in the state. Immigration to the US tends to concentrate in richer states – California, Hawaii, and New York rather than Kentucky, Tennessee, and West Virginia.

The Method of Bounds

In 1995 in the state of Washington, 8% of the population was foreign born, while 34% had high incomes. These are known. Let p be the fraction of the foreign-born who had high incomes, and let q be the corresponding fraction for the native-born. Investigators making ecological inferences would typically not know the fractions p and q. The two unknowns satisfy an equation:

$$0.08p + (1 - 0.08)q = 0.34 \qquad [2]$$

We have one equation with two unknowns: that is the whole problem of ecological inference. However, eqn. [2] does contain some information, because $q = (0.34 - 0.08p)/(1 - 0.08)$. Since p is bounded between 0 and 1, it follows that q is bounded below by $(0.34 - 0.08)/(1 - 0.08) \doteq 0.26$. Similarly, the upper bound is $0.34/0.92 = 0.37$. This is 'the method of bounds' (Duncan and Davis, 1953). Such bounds can be computed for each study area, and then aggregated. However, in typical applications, the bounds are too broad to be informative (also see Goodman, 1959).

Ecological Regression with Random Coefficients

Models with random coefficients have been used to make ecological inferences. By way of illustration, we consider a model for nativity and income. Index the study areas by i. As before, let x_i be the fraction of the population in area i that is foreign born, and y_i the fraction with high incomes. These fractions are known, as is the total population n_i of area i. Let p_i be the fraction of the foreign-born with high incomes, and let q_i be the corresponding fraction for the native-born, so

$$y_i = p_i x_i + q_i(1 - x_i) \qquad [3]$$

The problem is to make inferences about p_i and q_i. To solve such problems, King (1997) assumes the pairs (p_i, q_i) to be independent and identically distributed across the study areas. This is his version of the constancy assumption: the statistical behavior of a demographic group is not allowed to depend on area of residence. The parent distribution is taken to be bivariate normal, conditioned to lie in the unit square so that p_i and q_i are both between 0 and 1. The five parameters of this parent normal distribution can be estimated from the data by maximum likelihood, and estimates $(\widehat{p}_i, \widehat{q}_i)$ can be derived from eqn. [3]. Rates for each demographic group can then be estimated by addition over areas, as $\sum_i n_i \widehat{p}_i / \sum_i n_i x_i$ and $\sum_i n_i \widehat{q}_i / \sum_i n_i (1 - x_i)$, respectively. More complex models have also been developed.

To show the force of the constancy assumption, we can use the 'neighborhood model' which assumes that behavior is determined by geography not demography. Then $\widehat{p}_i = \widehat{q}_i = y_i$ for each study area i. (In our example of nativity and income, if

33% of the residents of a particular study area have high incomes, this percentage applies equally to the foreign-born and the native-born in that area.) The neighborhood model turns the constancy assumption on its head. In a variety of test applications where all the data are available, the neighborhood model gives more accurate estimates for demographic groups than ecological regression or random-coefficients models. In some contexts, of course, the neighborhood model proves deficient (Achen and Shively, 1995). If the data are incomplete so estimation is needed, it will be unclear which model if any is giving the right answers. The track record to date favors the neighborhood model (Freedman et al., 1991, 1998). For another perspective see Schuessler (1999).

Summary and Conclusions

Aggregate data are often easier to obtain than data on individuals, and may offer valuable clues about individual behavior. Ecological inferences will therefore continue to be made. The problems of confounding and aggregation bias, however, are unlikely to be resolved in the proximate future.

Ecological Social Work: Shifting Paradigms in Environmental Practice

Fred H Besthorn, School of Social Work, Wichita State University, Wichita, KS, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Conventional models of ecological social work have had profound staying power in the theoretical life of social work. They have become conventional wisdom for much of social work practice. In recent decades, however, a new ecological model has emerged. This new ecological model argues that the core values of social work and its conventional ecological models must be altered to support the new realities of the importance of the natural environment and the impending environmental crisis. This article traces the historical evolution of social work's conventional ecological thinking and traces the contours of a new ecology of social work.

Since the early 1960s, social work sought to establish a conceptual demarcation point between itself and other helping professions through reliance on ecological and environmental metaphors of practice. The language of person-in-environment, person-and-environment, or person/environment emerged as common representations in North America and in other parts of the Western world with respect to how the profession attempted to delineate the nature and focus of social work practice. In large measure, it was an attempt on the part of many social work theorists to summarize, with what appeared a simple and readily accessible vernacular, the unique niche and emphases constituting social work practice. Social work staked out its practice space at the interface of individuals in their unique environmental contexts.

This was not a particularly new development since the profession has, for the better part of its 100-year history, been characterized by alternating attempts to find common ground between personal responsibility and environmental circumstance. It can be seen from the very earliest years of the profession especially in the often stark dissimilarity between the individualistic and moralistic friendly visiting of Charity Organization Societies (COS) and the situational and contextualized in-place environmental change efforts of the Settlement House Movement. COS friendly visitors were tasked with investigating the circumstances surrounding the indigent person's need and to instruct poor people in ways to better manage their personal lives (van Wormer and Besthorn, 2011). The belief that individuals were morally responsible for their own circumstances was unambiguous. Intervention began and ended with the individual. On the other hand, Settlement House efforts were not that of friendly visiting, but rather, were infused with a genuine desire to bridge class differences and develop a more contextualized and less patronizing form of charity. The environment, not the individual person, was the locus of change for these workers. Settlement Worker's efforts to improve community sanitation systems, to alleviate the deplorable living conditions of tenement houses, and their efforts at developing park areas and green spaces for play and recreation were clearly focused on environmental conditions impinging on personal well-being.

Ecological Social Work: A Conventional Perspective

Throughout much of its recent history, social work has sought innovative ways to conceptualize the relationship between the individual and environmental contexts of human functioning and how professional practice engages with those dimensions. While the person-in-environment vernacular has proved a useful linguistic marker attempting to define the parameters of social work practice, not everyone has been convinced of its utility (Kemp et al., 1997). The problematic tension between operationalizing the interactive nature of person-and-environment intervention continued in US social work as an intermittent point of contention in much the same way as had been the case in the early decades of the twentieth century. In an attempt to clarify the perceived imprecision of person-and-environment metaphors and their lack of practical application for frontline social work practice, several North American social work theorists began to integrate ideas from the field of ecology into social work theory (Germain, 1968, 1973, 1978; Germain and Gitterman, 1980). What became popularly known as ecological social work gradually emerged out of a turbulent ideological legacy characterized by reoccurring struggles to realistically conceptualize a dual and balanced obligation to both person and environment. This incremental evolution toward an ecological social work was different in other parts of the social work world but may have followed a similar trajectory.

Ecological theories had been popular for some time in the fields of sociology, anthropology, and psychology prior to their introduction to social work. Carel Germain (1973) first introduced her ecological perspective to social work in part to acknowledge the growing trend to conceive of human development and deteriorating social and biophysical conditions in holistic and systemic terms. Germain understood that in order to fully enhance human well-being, the physical and social environments of persons must be assessed concurrently. Germain argued persuasively that ecological thinking helped social work conceptualize the world in organic terms. It was also more compatible with core social work values since it attempted to integrate broader ecological systems with the lived experience of human beings (Kemp et al., 1997).

Later, Carel Germain collaborated with colleague Alex Gitterman (Germain and Gitterman, 1980) to elaborate on her earlier ecological perspective. Their Life Model of Social Work Practice attempted explicitly to apply ecological principles to direct practice. The life model, while going through several iterations over past decades (Gitterman, 2011), recognized the importance of a goodness of fit between people and their environments, which allows both reciprocally to respond and adapt to one another. The life model relies heavily on ecological concepts and metaphors to emphasize the transactions between people and environments. Human development is characterized by complex processes that emerge, change, and evolve over time. Persons and environments never stand in static relationship to each other. The life model conceives of problems in living as a result of stress associated with inadequate fit between people and their environments. These problems revolve around stressful life transitions, maladaptive interpersonal processes, and environments that become or remain unresponsive despite human intervention to modify and improve them.

Carol Meyer (1979, 1983) introduced a variant of Carel Germain's ecological perspective called the ecosystems perspective. Her work was an explicit attempt to find a unifying framework to guide practice, which combined elements of both systems and ecological theory. Carol Meyer conceived of her ecosystems perspective as a conceptual framework – a kind of metamodel – rather than a fully operationalized theoretical position. She suggested that the ecosystems perspective "offers social work practitioners/clinicians a way of thinking about and assessing the relatedness of people and their impinging environments: it does not specify the what (problem-definition) or the how (methodology) of practice" (Meyer, 1983: p. 29). Similar to Carel Germain's earlier ecological perspective, the ecosystem perspective drew the profession's attention not only to persons-in-environments but to the dynamic interactions of persons and environments. These interactions are constant and nonlinear and, from an ecosystems perspective, no simple cause and effect explanation can ever serve to understand the complexities of the human condition.

Conventional models of ecological social work have had profound staying power in the theoretical life of social work. They have shaped the emergence of what many have commonly come to call ecological social work (Greene, 2009; Hutchinson, 2011; Rogers, 2011). These models have become conventional wisdom for much of social work practice. Over the last several decades, ecological perspectives have been widely utilized in social work education and practice. Many social work practice and human behavior textbooks are grounded in various dimensions of ecological theory (Hutchinson, 2011; Rogers, 2011). One would be hard pressed to find a significant number of social workers who do not, at some level, ascribe to at least the basic tenets of ecological social work theory. The purpose of social work practice from a conventional ecological perspective is, in the main, to enhance the goodness-of-fit between individuals and their environments and by so doing increase personal and social capacities either to find resonance with, influence, or change environmental factors (van Wormer and Besthorn, 2011; Payne, 2005). The influence of conventional notions of ecological social work, both in North America and around the world, cannot be underestimated. Ecological social work, as conventionally conceived, ushered in a new integrative paradigm for a profession that had struggled for decades to conceptualize its obligations to both person and environment (Dominelli, 2012). As Katherine van Wormer and Fred Besthorn (2011: p. 19) note with respect to conventional ecological models of social work practice in the United States, "no other conceptual frame of reference since the introduction of Freudian psychology has had as significant an impact on mainstream social work thinking as have the ecological and systems formulations."

A New Ecological Social Work: An Alternative Ecological Paradigm of Nature

The profession's conventional ecological perspective has been relevant to social work in that it provided a comprehensive, multidisciplinary, and holistic framework within which the complex and interrelational elements of persons' lives could be connected and understood. Conventional ecological social work ushered in the first meaningful attempt to integrate the psychological and sociological dimensions of social work practice and supported a conceptual "shift in social work practice from a static to a dynamic view of the environment" (Kemp et al., 1997: p. 41). In reality, social work had always, to a greater or lesser extent, been concerned with situational determinants of human functioning. But, until the evolution of the ecological perspective the profession found it easier, and often more expedient, to address personal functioning. The environment seemed just too amorphous and the task of changing it seemed too daunting.

While social work spoke the ecological and systems language of environments in interaction, in reality the focus was mainly on individual behavior in static environments. This severely limited the profession's capacity to engage critically with those structural barriers marginalizing oppressed groups. Additionally, to a new generation of social workers, it hindered a response to deteriorating natural environments and their catastrophic impact on clients' lives. Indeed, one of the persistent criticisms of social work's conventional ecological perspective has been its rather narrow interpretation of the environmental construct. As early as the 1960s, some social work scholars had become critical of the profession's conceptualization of environment (Stein, 1963). In particular, Richard Stein identified three major shortcomings associated with the concept. First, he noted the tendency to regard the environment as very narrowly related to immediate contexts such as housing, jobs, communities, families, social relationships, and face-to-face interactions. Second, he identified the inclination to view environment as external and only peripherally related to the individual who "stands alone, an isolated complex of intra-psychic processes" (Stein, 1963: p. 68). Third, Stein noted the tendency to view the environment as backdrop – static, unchanging, background clutter. Richard Stein argued that social work's efforts with respect to and on behalf of the

environment was truncated and merely a second-rate activity compared to the more important skill of psychosocial treatment. Thus, despite the rhetoric of persons and environment in dynamic interaction, the environment was still interpreted as a relatively benign, circumstantial space that persons either adapted to or learned to negotiate. Consequently, ecological social work in practice fell back upon the profession's historic tendency to emphasize heavily individual function in an environment that was generally resistant to change and was likely to impinge upon optimal coping capacity.

Criticisms that social work's conventional ecological perspectives and environmental definitions unnecessarily restricted the definition of the environmental construct were relatively new to social work's scholarly discourse. Several social work scholars (Weick, 1981; Resnick and Jaffee, 1982; Soine, 1987; Gutheil, 1992; Saari, 1992; Berger and Kelly, 1993; Hoff and Polack, 1993; Rogge, 1993) began to argue that the core values of social work and its conventional ecological models must be altered to support the new realities of the importance of the natural environment and the impending environmental crisis. They reiterated what Richard Stein (1963) noted some 30 years earlier, that social work spoke the ecological language of environments in interaction but, in reality, the focus was mainly on individual behavior in static, narrowly construed environments. However, they also noted that conventional ecological models seriously inhibited conceiving the natural environment as anything more significant than data to be studied or resources to be procured or regulated. Social work's uncritical adoption of the adaptive, static, and narrowly defined notions associated with conventional ecological thinking had unwittingly conspired in creating a state of collective consciousness suggesting that a person exists on a plane of deep division between oneself and one's place in the larger natural world. Person-in-environment from a conventional ecological perspective had become a kind of euphemism for what was, in reality, persons living in an environment that was wholly separate and distinct from them. Deeper understandings of identity with nature is then excluded and becomes an abstraction that leads to concepts and actions that cannot be reconciled with either the health of persons or of nature. Living in nature, on the other hand, suggests a complex relationship melded together over time through patterns of value, memory, familiarity, love, and respect.

By suggesting that an alternative ecological model of social work must also consider the natural world, these scholars were also suggesting something quite new to social work. Their critique was not just about extending conventional environmental definitions to include the natural world but, in many ways, to advocate for a radical new approach in how social work conceived itself and how it went about its practice priorities. For a small but growing number of social work scholars, especially in the Western world, the recognition began to emerge that the natural environment shares a complex and evolutionary link to personal, social, cultural, and transpersonal developments. They began addressing the implications of nature's degradation, especially on poor and vulnerable populations, while at the same time exploring the natural world's ethical, aesthetic, mythic, and therapeutic influences and capacities to inform social work theory and practice. For these scholars, social work could no longer afford to view the natural environment as a backdrop to other matters but as the centerpiece for the core values, purposes, and functions of social work. Human social development and human suffering could not be fully understood or effectively addressed until the profession recognized that the human world was integrally related to, dependent upon, and emergent from the natural world.

Thus, in the last 15 years, a new generation of social work theorists and practitioners extended the original parameters of conventional ecological social work to include a broader definition and more profound understanding of the interaction between person and environment. Due in large measure to the emergence in the 1980s and 1990s of the worldwide environmental movement, a new form of ecological social work began to take shape. With the release of Maria Hoff and John McNutt's (1994) edited anthology, social work had its first well-organized and thoroughly reasoned statement of principle, premised on the ideal that ecologically minded social work could not fully realize its stated commitment to person-in-environment until it seriously considered the inseparable link between human well-being and the well-being of the planet. Maria Hoff and John McNutt (1994) argued that earth's ecological systems were not static but, rather, consisted of several interconnected layers including the geosphere, hydrosphere, atmosphere, biosphere, and noosphere. The first several of these refer to facets of the soil, water, air, and biological systems, which support or impinge on human well-being. The noosphere, on the other hand, represents a deeper, atavistic, and perhaps even a genetically predisposed connectedness with nature that lies beyond physical dependence but that is nonetheless absolutely indispensable for human development and survival (Besthorn and Saleebey, 2003). Shortly thereafter, another wave of social work scholars including John Coates and Marilyn McKay (1995), Mary Rogge (1996), and Fred Besthorn (1997) were among the first social workers in North America to begin a thorough critical analysis of the theoretical and practical linkages between planetary consciousness and social work.

Since then, there has been a flowering of published works on the interrelationship between the natural environment and the theory and practice of social work (Global Alliance for a Deep Ecological Social Work, 2012). A growing core of social workers from North America, Europe, and Australia began to speak compellingly concerning the importance of incorporating the natural environment into the profession's theoretical formulations and practice modalities (Besthorn, 2001, 2002, 2008, 2012, 2013; Besthorn and McMillen, 2002; Besthorn and Meyer, 2010; Borrell et al., 2010; Coates, 2003, 2005; Coates et al., 2006; Dominelli, 2012; Gray et al., 2012; Hawkins, 2010; Jones, 2006, 2010; Lysack, 2007, 2010; Mary, 2008; Matthies, 1987; Matthies et al., 2001; McKinnon, 2005, 2008; Molyneux, 2010; Muldoon, 2006; Narhi, 2004; Peeters, 2011, 2012; Power and Freedman, 2012; Rogge, 2008; Rogge and Combs-Orme, 2003; Rotabi, 2007; Ryan, 2011; Shaw, 2006, 2008; Ungar,

2002, 2003; West, 2007; Zapf, 2008, 2009). In an attempt to differentiate it from social work's conventional ecological frameworks, this emerging alternative ecological perspective of social work has been referred to in several different ways (e.g., environmental social work, ecosocial work, deep-ecological social work, ecospiritual social work, and green social work). For its advocates, this alternative ecological perspective better positions a profession, often conspicuously absent, in the emerging international consensus that Earth's ecosystems and its capacity to support life are in deep trouble. Until the profession began to take seriously the importance of the natural world in its understanding of social work, the profession could not fully realize its core commitment to person-and-environment.

A New Ecological Social Work: Major Scholarly Themes

It would be difficult to fully catalog the many differing thematic areas of research interest that scholars and practitioners operating from a new paradigm of ecological social work have addressed over the last decade. It would also be beyond the scope of this article to describe in detail the key thematic areas that have contributed to the discourse of a new ecological social work. Social workers committed to incorporating nature and deeper ecological thinking into practice will likely have varied and unique interests. However, a cursory review of the recent new ecological social work literature does suggest a number of overarching themes. In general, these include discussions of

1. the comparative importance of incorporating nature into the practice of social work
2. social work's historical attempts at integrating ecological theory into its theoretical and practice frames as well as critiquing social work's conventional person-in-environment perspective
3. the ontological, axiological, and epistemological basis upon which a new ecological social work might be supported
4. the interface between economic development, ecological sustainability, economic globalization and strengthening social capital as a catalyst for creating sustainable livelihoods and community security
5. the importance of grassroots initiatives to spur involvement of communities in the creation of ecological awareness, sustainable development, and food security
6. the interface of fossil fuel dependence and the carbon-based economy and its deleterious impact on energy conservation and sustainability, especially with low-income and marginalized persons and communities
7. how extractive mining practices and industrial damage carried out by transnational corporations impact small communities and dependent workforces
8. the importance of crisis intervention in disaster and traumatic stress events including natural and human-induced disasters
9. social work interventive strategies and efforts in drought-stricken areas of the world
10. the importance of social work's involvement in grassroots activism especially with respect to climate change and the increasing severity of climatic events
11. social work responses to toxic waste exposure in low-income communities
12. social work responses to the growing crisis of 'environmentally displaced persons' – sometimes inaccurately referred to as environmental refugees
13. the application of deeper ecological thinking to therapeutic practice with individuals, groups, families, and communities
14. the interface between social and ecological justice and the importance of shifting from an anthropocentric to an ecocentric basis for determining just priorities and actions
15. the application of principles of a new ecological paradigm to social work education and curriculum development
16. the importance of honoring indigenous ways of knowing relative to the natural world and how these might help inform the evolution of a new era of best practice in social work
17. social worker's involvement in the utilization of animal-assisted activities to enhance the quality of life of individuals and groups
18. social worker's involvement in the utilization of nature-assisted activities and programs such as Outward Bound, Plant-People Council, and Project Adventure to enhance life quality for individuals and groups
19. the interrelationship between spirituality, religion, and deeper ecological consciousness and ways to incorporate transpersonal ecological ideas into social work theory and practice.

A New Ecological Social Work: Core Operational Values

Social work has often been described as a value-laden profession. Many major social work institutional mission declarations describe core values that establish a framework for effective social work practice. For example, in the United States, the National Association of Social Work (NASW) identifies six core values that are thought critical to the practice of effective social work. Unfortunately, the same cannot be said for the emergence of a new ecological social work model. With the exception of a small number of general statements of principle by several national and international social work associations (e.g., NASW, International Federation of Social Workers, and International Association of Schools of Social Work); few, if any, explicit statements exist that attempt to create a compendium to core values that many, if not most, environmental social workers might identify with. Like the diversity that exists in the thematic areas of scholarly interest, the assortment of opinion of what constitutes the core values of a new ecological perspective is quite multifaceted. This is not to say that there are no statements of principle of core values that many social work scholars have propounded as important to the emergence of a new ecological perspective. The literature is replete with

ample discourse addressing a multitude of values and principles thought by their respective authors to be critical to advancing and sustaining a new ecological perspective (Coates and Gray, 2012; Dominelli, 2012). The issue has always been in systematizing and categorizing these ideas into some accessible and reasonably clear framework. The following is a brief listing, from this author's perspective, of those core values common to a new ecological model of social work. The shift toward the new ecological paradigm is a gradual process that has been occurring as more people begin to think systemically and, no doubt these are likely to change as new scholarly and practice agendas mature.

1. The belief that it is impossible to fully comprehend the complexity of ecosystems and the human condition in conventional linear, atomistic, and mechanistic terms. Intuitive ways of knowing, nonlinear thinking, and emotional intelligence are seen as valid routes to knowledge along with rationality and experimentation
2. an understanding that the conceptualizations of environment includes all beings and systems in the cosmos – human and nonhuman – as well as the idea that humans can be aware of, and connected to, all these levels of being; environment is far more than the social milieu
3. the importance of affirming the need to live in harmony with nature, each other, and the entire planetary ecosystem
4. the importance of seeing humankind as intimately connected (biologically, genetically, aesthetically, economically, and historically) with the natural world, as, indeed, natural beings themselves who are inseparable from the unity of all things and beings
5. the importance of ascertaining and applying the wisdom of nature and with seeing nature as fecund source of intelligence that has guided and must still guide humanity's understanding of itself and the interconnected nature of interactions among and between all organisms
6. the importance of developing an ecocritical analysis of Western modernity's deeply entrenched social, political, ideological, and economic assumptions that have led to a myopic preoccupation with unrelenting progress, unrestrained development, unending consumption, and unremitting despoliation of the earth's carrying capacity
7. the necessity of adhering to the idea of long-term sustainability that sees the earth as a balanced system, that requires humans to be intentional about preserving and maintaining the necessary conditions for sustaining quality life for both humans and the nonhuman world
8. the belief that the shift to a new ecological paradigm requires nothing short of a radical and wholesale transformation of global human consciousness away from its anthropocentric bias toward an ecocentric orientation.

A New Ecological Social Work: Future Prospects

A new ecological model of social work is, in general terms, predicated on the assumption that there is much that can and must be done to address looming and potentially catastrophic environmental problems. Social work has opportunities to contribute to a transformed world. Some of those opportunities have already begun with the ideas, findings, and insights that social work researchers, scholars, and practitioners have obtained, which have been alluded to in the earlier sections of this article. But, the future of a new ecological model of social work depends on professionals overcoming the general social tendency to minimize the seriousness of environmental concerns while convincing oneself that social work professionals have a role to play in addressing these issues. Involving our professional lives in these concerns and crafting our theoretical and practice models in comprehensively earth-centered terms can be politically and professionally risky for social workers. The fear for some is that too close an identification with highly charged social causes runs the risk of social work losing its credibility as objective investigators and socially responsible change agents. And yet, when has this not been a risk for social work? As a profession, social work has routinely identified with risky, politically charged issues for the improvement of individual clients, marginalized groups, and the larger social order, generally. The difference is that which is currently marginalized is the very natural, planetary system that all depend upon for survival. Inattention and hoping for the best can no longer be justified. At the heart of the question for social work is how it participates in and encourages those transformations necessary to protect fragile environments, reverse ecosystem degradation, and once again live in unity with other living things. A new ecological model of social work holds great future promise to bring the profession closer in line with the emerging global momentum toward ecological and economic sustainability, full democratic participation, unadorned sufficiency, and a post-anthropocentric solidarity with the natural world.

A new ecological model of social work presents a thorough organicist worldview with respect to both people and environments as living systems in dynamic interaction with each other. The primary importance of this alternative ecological perspective is that it can be incorporated into many levels of practice. Whether at the level of assessment, individual, community, organizational, or political practice, a new ecological perspective provides an intelligible framework for viewing person and environment interaction as well as the prospect for better outcomes associated with comprehensive multidimensional interventions. Social workers could, if they wished, enter into this organic milieu and pursue interventive strategies that either help change or remove environmental obstacles to enhanced personal growth and adaptive capacity.

This article is a revision of the previous edition article by D. Stokols, volume 6, pp. 4030–4035, © 2001, Elsevier Ltd.

Abstract

Ecology pertains broadly to the relationships between organisms and their environments. The field of ecology and health examines the influence of conditions in the physical and sociocultural environment on the physiological, social, and emotional well-being of individuals and groups. The present article traces the development of research on ecology and health, beginning with the emergence of the ecological paradigm in the biological sciences and its subsequent development in other disciplines, including sociology, psychology, and public health. Recent interpretations of ecology as it applies to human health emphasize a perspective that acknowledges humans as an integral and interdependent part of the larger global ecosystem.

Ecology and Health

The term 'ecology' pertains broadly to the interrelations between organisms and their environments (Hawley, 1950). From its early roots in biology, the ecological paradigm has evolved within several disciplines (e.g., sociology, psychology, economics, and public health) to provide a general framework for understanding people's transactions with their physical and sociocultural surroundings (e.g., Barker, 1968; Bronfenbrenner, 1979; Park et al., 1925). The field of ecology and health examines the direct and interactive effects of conditions in the physical and sociocultural environment on the physiological, emotional, and social well-being of individuals and groups (cf Duhl, 1996; Moos, 1979; Stokols, 1996). Ecological analyses provide more integrative and comprehensive explanations for the joint influence of biogenetic, psychological, behavioral, sociocultural, and physical environmental factors on human well-being, than do narrowly gauged biomedical, behavioral, and environmental theories.

Emergence of Ecological Perspectives on Health and Illness

The emergence of an ecological paradigm for understanding the determinants of health and illness in human populations can be traced to research developments in several scientific fields. During the 1920s and 1930s, a series of correlational analyses were conducted by researchers in the Chicago School of Human Ecology, revealing systematic associations between community rates of illness and crime on the one hand and physical and social conditions of the urban environment (including poor-quality housing and high population densities within residences and neighborhoods) on the other hand (cf Faris and Dunham, 1939; Park et al., 1925). These correlational studies in the fields of human ecology and sociology suggested a strong link between conditions of the urban environment and residents' health, but did not provide an integrative theoretical account of the causal pathways connecting those variables.

An important theoretical analysis of the links between the social environment and illness etiology was provided by John Cassel in the field of public health. Cassel's (1964) conceptualization of social epidemiology signaled a shift from 'germ-theory' accounts of health and illness (focusing on the health-impairing effects of specific pathogens once they invaded a human 'host'), toward a more ecologically oriented, contextual perspective emphasizing the effects of one's social environment (e.g., work overload, sources of interpersonal stress) on immune functioning and host resistance to pathogenic agents. Cassel's formulation of social epidemiology during the 1960s and his hypotheses concerning the impact of social and cultural factors on human health have been corroborated empirically in subsequent studies linking job strain, social isolation, and interpersonal stress to a variety of illness conditions and premature death (cf Berkman and Syme, 1979; Karasek and Theorell, 1990; Marmot et al., 1997).

Incorporation of the ecological perspective into areas of health promotion initially perceived as rooted in individual behavior and therefore best targeted by individual-focused behavior change strategies has led to an ecological approach to public health. Publication of the US Surgeon General's Reports in 1964 and 1979, documenting the deleterious effects of smoking on health, prompted the rapid growth of health promotion and disease prevention research during the 1980s (cf US Public Health Service, 1979). Much of the early research in this field was rooted in the concepts and methods of health education, and focused largely on behavior change strategies aimed at fostering healthier lifestyles and health habits among individuals (cf Belloc and Breslow, 1972). As appreciation for the salient role played by societal and environmental influences grew, efforts to encourage health-promoting behavior took a decidedly ecological turn, with programs such as ASSIST, an ambitious government-funded demonstration project undertaken in the 1990s to help states develop effective strategies to reduce smoking. Focusing on policy change, the goal of ASSIST was to alter states' social, cultural, economic, and environmental factors that promote smoking. Results of the evaluation of ASSIST supported the ecological hypothesis that policy-level changes can be effective for promoting changes in individual health behavior (Stillman et al., 2003).

Such targeted efforts to enhance individuals' health behaviors via an ecological approach have led to reduced use of tobacco products among adults, lower rates of alcohol-related automobile deaths, and reduced employee health costs at the

worksite (cf McGinnis and Lee, 1995; Pelletier, 1996; Schneider and Stokols, 2008). At the same time, however, the ecological approach to understanding health and disease has led to increased awareness of health risks that are strongly influenced by conditions outside of individual control, such as exposure to community violence, lack of medical insurance, environmental injustice, poverty, and unemployment. Critically, many of these health risks remain segmented in hard-to-reach 'pockets of heightened prevalence' (Fisher, 1995) – especially among low-income and minority groups in the population (cf Adler and Stewart, 2013; Bullard, 2005).

Growing recognition of the limitations associated with behavior change programs has prompted a paradigm shift in the health promotion field, away from individually focused interventions toward more comprehensive, ecological formulations that address interdependencies among socioeconomic, political, environmental, organizational, biological, and psychological determinants of health and illness (cf Kickbusch, 1989; Schneider and Stokols, 2000; Winett et al., 1989). These strategies include increased resources devoted to community policing as a method of preventing neighborhood violence (MacDonald, 2002), diversion of convicted drug users to treatment programs (Bull, 2005), and the Affordable Care Act, which utilizes a legislative approach to persuading individuals to purchase health insurance (Lavarreda et al., 2011). A common feature of these programs is that they incorporate multiple levels of analysis and intervention components – including political action, legislative reform, media advocacy, as well as behavioral change and environmental enhancement efforts – to address key contextual factors that substantially influence individual and population health.

Whereas the ecological approach to health has been informed and influenced by the principles of community health/community psychology, the former extends beyond the latter on both ends of the continuum from more proximal factors (e.g., biologic, genetic, and other intrapersonal factors) to more distal factors (e.g., global or national conditions). Community health, in which formal or informal social groupings form the unit of analysis or of intervention, may be viewed as a particular application of the ecological paradigm, which represents a "unique way of looking at the world" (Kelly, 2006). According to the ecological approach, health is "viewed as the consequence of reciprocal causation unfolding at multiple individual and environmental levels of influence" including, but not limited to, the community (cf Richard et al., 2012).

One other major development that has prompted greater interest in ecology and health in recent years is the discovery of adverse global environmental changes – for instance, the depletion of atmospheric ozone and the trend toward climate change – which have the capacity to elevate population morbidity and mortality rates at worldwide as well as regional and national levels (cf Folke, 2006; Stern et al., 1992; Stokols et al., 2009). Potential health impacts of these global changes include elevated skin cancer rates resulting from ozone depletion and individuals' heightened exposure to ultraviolet rays, and the food shortages, nutritional ailments, and respiratory illnesses associated with climate change (cf Leaf, 1989). The health consequences of extreme weather and disasters, expected to increase in both frequency and severity as the climate shifts (IPCC, 2012), are becoming more evident as well. The discovery of these global environmental threats to population health has prompted greater international collaboration in the development of ecologically oriented health promotion programs through programs such as the World Health Organization (WHO) Healthy Cities Program (cf Ritsatakis, 2012) and the WHO work plan on climate change and health.

Core Principles of Ecology and Health Research

Research on ecology and health encompasses several disciplines, including medicine, public health, urban planning, environmental design, public policy, and the behavioral, social, and global ecology sciences. The scientific contours of this research are not easily delimited, owing to the interdisciplinary scope of the field (cf Stokols, 2000). The unique concerns of ecology and health can be better understood in terms of the overarching conceptual principles that underlie this field, rather than by searching for a clearly defined body of research organized around this topic. The core principles underlying ecology and health research are drawn largely from programmatic statements about the 'New Public Health' and the conceptual and methodological assumptions of systems theory and social ecology (cf Duhl, 1996).

Intellectual Antecedents: Systems Theory and the Ecological Paradigm

The 'New Public Health' outlined in the Ottawa Charter for Health Promotion (1986) called for the development of comprehensive, ecologically oriented approaches to the study and prevention of disease (cf Kickbusch, 1989). For instance, the Ottawa Charter gave explicit attention to social causes of illness, as well as the physical environmental health threats that exist in many communities. Subsequent analyses of ecology and health extended these programmatic ideas by providing a set of conceptual and methodological principles derived largely from systems and ecological theories, for organizing and evaluating community-based health promotion programs (cf Green and Ottoson, 1999; Sallis et al., 2006).

The field of ecology and health incorporates a number of concepts derived from systems theory (e.g., interdependence, homeostasis, negative feedback, deviation amplification; cf Emery and Trist, 1972; Maruyama, 1963) to understand the interrelations among people and their environments. Systems analyses suggest that the healthfulness of particular settings and the well-being of their participants are jointly influenced by multiple facets of the physical environment (e.g., geography, architecture, technology) and the social environment (e.g., culture, economics, politics). The health status of individuals and groups is further influenced by personal attributes such as genetic heritage, psychological dispositions, and behavioral patterns. From the vantage point of systems theory, efforts to promote well-being should be based on an understanding of the relationships among diverse environmental and personal factors, rather than on analyses that focus exclusively on environmental, biological, or behavioral factors (cf Moos, 1979).

Research Findings from Ecological Analyses of Health

The direct and interactive effects of environmental and personal attributes on health have been observed in several lines of research. For example, a substantial body of research highlights the ways in which poverty, inequality of income distribution, and minority status jointly undermine the health of individuals and vulnerable subgroups in the population (cf Adler and Stewart, 2013; Bullard, 2005; Kaplan et al., 1996). Other studies indicate that neighborhood socioeconomic status (percent of households in a geographic area receiving public assistance) is associated with poorer self-reports of health, above and beyond individual socioeconomic status (Malmstrom et al., 1999; Robert, 1998). Interactive effects of environmental and behavioral risk factors are exemplified by the findings that environmental exposure to asbestos exacerbates chronic smokers' risks of developing lung cancer (Grunberg, 1991), and that an individual's disposition toward exerting internal control over his/her environment buffers the potentially negative effects of low education and income on health status (Lachman and Weaver, 1998).

Systems theory also posits that people–environment transactions are characterized by cycles of mutual influence, whereby the physical and social features of settings directly affect occupants' health and, concurrently, the participants in settings modify the healthfulness of their surroundings through their individual and collective actions (or, alternatively, adopt an increasingly passive stance toward their environment). For example, individuals' routine exposure to community violence in some low-income neighborhoods can provoke feelings of disempowerment, helplessness, and depression, which in turn diminish their efforts to adopt health-promotive practices related to physical activity and dietary change (cf Sanders-Phillips, 2000). In contrast, local residents' struggles with asthma exacerbated by air pollution can motivate them to engage in community activism targeting policies that impact air quality (Garzón et al., 2012). On a societal level, economic forces have stimulated an accelerated process of urbanization and commensurate degradation of the natural environment – a change that may be associated with poorer health status and that some communities attempt to counteract with urban planning that preserves greenspace for parks (Maller et al., 2008). Accordingly, ecological analyses of health should take into account that persons and their environments are in a constant state of mutual adaptation.

Ecologically oriented studies of health also incorporate certain conceptual and methodological principles drawn from the field of social ecology (Stokols et al., 2013). For instance, ecological theory highlights the multidimensional nature of human environments. Environmental settings can be characterized in terms of their physical and social components, their objective (actual) or subjective (perceived) qualities, and their scale or immediacy to individuals and groups (proximal vs distal). Moreover, the participants in environmental settings can be studied at varying levels ranging from individuals, small groups, and organizations, to larger communities and populations. Rather than focusing solely on individuals or aggregates, the social ecological perspective incorporates multiple levels of analysis and diverse methodologies (e.g., medical exams, questionnaires, behavioral observations, environmental recordings, epidemiologic analyses) for assessing the healthfulness of settings and the well-being of individuals and groups.

Social ecological analyses conceptualize human environments as complex systems in which local settings and organizations are nested within more complex and remote regions. Accordingly, efforts to promote human well-being must take into account the interdependencies that exist among immediate and more distant environments. The occupational health and safety of workplaces at the local level, for example, are directly influenced by state and national ordinances aimed at protecting environmental quality and public health (cf Stokols, 1992).

Another core theme of ecological theory is that physiological, emotional, and social well-being are influenced by the multiple, interrelated settings that comprise the daily activity systems of individuals and groups (cf Michelson, 1985). Bronfenbrenner's (1979) ecological model of human development highlights the joint influence of people's families, school, work, and recreational settings on their health and developmental outcomes. Rather than focusing exclusively on person–environment transactions that occur within single settings (microsystems, such as home or work environment), Bronfenbrenner's research emphasizes the ways in which functional linkages between two or more settings (i.e., the mesosystem, the exosystem, and the macrosystem) influence developmental processes and outcomes. Mesosystem units are comprised of two or more environmental settings (e.g., family and occupational environments) in which the individual is directly involved (e.g., a parent employed outside the home). Exosystems include an environment in which the developing person is directly involved (e.g., a child in his or her home environment) and one or more other settings in which that person does not participate directly (e.g., the workplaces of the child's parents), but that, nonetheless, affect his or her development and well-being (e.g., stressful experiences at work that impair the quality of parents' interactions with their children at home). Finally, the macrosystem level of analysis encompasses the belief systems, social norms, and institutions of the culture as a whole.

The joint influence of multiple life settings on individuals' health has been observed in several studies. Children's exposure to environmental stressors (such as high levels of spatial density and noise) in their home and elementary school environments, for instance, was associated with both additive and interactive effects of those conditions on their physiological health (e.g., systolic and diastolic blood pressure) and academic achievement (cf Cohen et al., 1986). In other studies, employees' perceived lack of flexibility in work hours for scheduling children's doctor visits was associated with their underutilization of employer-provided family health benefits (Fielding et al., 1994). Health outcomes associated with the work–family mesosystem have also been documented through studies of the adverse impacts of 'work–family conflict,' as well as the positive effects of spousal support in buffering work-related stressors (cf O'Neil and Greenberger, 1994).

The research findings noted earlier suggest the value of studying human health from an ecological systems perspective. By considering the joint influence of multiple life settings on individuals' well-being, a broader understanding of how

personal and situational factors contribute to health status can be achieved, than by focusing more narrowly on environmental conditions within single settings.

Directions and Challenges of Ecology and Health Research

The broad conceptual scope of ecology and health research is both an asset and a limitation. On the one hand, the breadth of ecological analyses affords a more comprehensive understanding of the multiple determinants of well-being. For instance, major political, economic, and environmental determinants of health that were neglected in earlier behavioral and medical studies yet have been targeted in more recent ecological analyses. On the other hand, so many disciplines and levels of analysis are combined in ecological research that it is difficult to achieve parsimonious explanations of health phenomena. Thus, an important challenge facing the field of ecology and health is to develop criteria for identifying the most influential determinants of wellness at particular levels of analysis (intrapersonal, social, organizational, institutional, community, global) and to give greatest priority to these high-leverage variables when designing scientific studies and community health promotion programs (see Health Education and Health Promotion).

A rapidly growing area of health research focuses on the impacts of individuals' virtual ecology on their physical, social, and emotional well-being (cf Stokols, 1999). Studies in this area have documented potential conflicts inherent in people's immersion in virtual settings and digital communications (e.g., chat rooms, multimedia multitasking, use of cell phones) while they are concurrently engaged in place-based relationships and behavior settings (cf Pea et al., 2012). For instance, the effects of perceived information overload from cybersources on individuals' self-reported levels of stress and health impairment (Misra and Stokols, 2012), and physical injuries resulting from multimedia multitasking while walking or driving, have been examined (Meyers, 2013; Strayer and Drews, 2007). At the same time, positive influences of the Internet on personal and community health, through telemedicine, telewellness, and the use of personalized mobile communications for health promotion and disease prevention have been identified (Stokols et al., 2009).

Developing High-Leverage Strategies for Effective Health Promotion

Examples of high-leverage variables and health promotion strategies include (1) the implementation of strategic corporate and public policies that can enhance population health on a broad scale (e.g., California's Proposition 99 which imposed a $0.25 tax on each pack of cigarettes sold and thereby reduced statewide levels of smoking prevalence (cf Breslow and Johnson, 1993)); (2) the modification of 'other-directed' health behaviors enacted by corporate and public decision makers whose actions directly influence health outcomes among large numbers of their employees and constituents (cf Stokols, 1996); (3) the identification of key socioeconomic indicators (e.g., female participation in the work force, unemployment, per capita government spending on health care) associated with rates of suicide (Milner et al., 2012); (4) the implementation of defensible space design guidelines to reduce the incidence of violence and crime in urban neighborhoods (cf Newman, 1972); and (5) the development of internet-based 'telewellness' programs designed to enhance health awareness and well-being among large segments of the population (cf Stokols, 1999).

Targeting Vulnerable Subgroups in Health Promotion Programs

An important direction for future ecological research is to incorporate the above leveraging strategies into the design of community health promotion programs aimed at improving the well-being of impoverished and underrepresented groups. Certain illness risk factors, including environmental racism, exposure to community violence, and lack of medical insurance, have proven to be highly resistant to earlier and more traditional health promotion programs (cf Bullard, 2005; Fisher, 1995). These interrelated community problems, borne disproportionately by low-income minority groups in the population, are highly complex and will be reversed only through the design and implementation of strategically leveraged, multilevel intervention programs (Winett et al., 1989), for example, the multisectoral Healthy Cities Programs sponsored by the World Health Organization (cf Ritsatakis, 2012).

Conclusions

The field of ecology and health, which grew rapidly during the last three decades, highlights the importance of developing integrative, broad-gauged strategies for promoting human wellness. As proponents of ecological analyses have noted aptly, improvements in individuals' health practices "usually require some combination of educational, organizational, economic, and environmental interventions in support of change in both behavior and conditions of living" (Green et al., 1997: p. 125). The principles of systems theory and social ecology outlined earlier provide a useful framework for establishing more integrative and effective approaches to wellness promotion in the coming decades.

This article is a revision of the previous edition article by H.-W. Wahl, volume 6, pp. 4045–4048, © 2001, Elsevier Ltd.

Abstract

The ecology-of-aging paradigm emphasizes the role of the physical, spatial, and technological environment on behavior and aging well. This work reviews the historical development of this field of study and defines its role within aging research in general. Furthermore, major theories and findings of the ecology of aging are summarized and discussed. The article closes with future considerations and unmet research needs.

The ecology of aging basically draws upon the idea that old age is a period of adult development profoundly influenced by the environment. Because age-related losses in vision, hearing, mobility, and cognitive capacity have a direct impact on the relationship between the organism and the environment, the older person is particularly vulnerable to environmental demands. In other words, the ecology of aging views contextual factors, particularly the physical, spatial, and technological environment, as crucial determinants of the autonomous exertion of everyday behavior and well-being. According to Lawton and Nahemow (1973: p. 621), the ecology of aging is defined as "a system of continual adaptation in which both the organism and the environment change over time in a non random manner." That is, both the aging person as well as his/her environment may influence each other in various ways and the outcomes of this reciprocal process may serve or hinder autonomy and well-being. Given its emphasis on the physical, spatial, and technological environment, the ecology of aging also is an important addition to aging research focusing on the social context (Wahl and Lang, 2006). Thus, although the term environment, as used in the ecology of aging, predominantly refers to the physical environment, its interwoven nature with social and cultural accoutrements and implications is also acknowledged. Importantly, person-environment relations have not only an objective but also a subjective dimension (Oswald and Wahl, 2005). Aging individuals, not the least because they live for long time at the same place, form strong cognitive and affective ties to their environments and in many cases (e.g., when relocation to a nursing home arises as a key residential decision) such cognitive-emotional ties seem to be more important than objective environmental characteristics.

Development of the Field

Since aging has long been regarded as a process mostly determined by a biological program inherent in the organism, the explicit consideration of environmental variables that affect the course and outcome of human aging was an important step in the historical development of aging research. This paradigm shift was and continues to be influenced by the following:

1. The Chicago School of Urban Sociology and its human ecology perspective (Burgess, McKenzie, and Park) in the 1920s and 1930s, the writings of Lewin in the 1930s and 1940s as well as the emergence of ecological psychology and of the social ecology view of human development (Barker, Bronfenbrenner, and Moos) in the 1960s and 1970s, which, among other things, placed particular emphasis on the resource character of the physical and spatial environment and hence provided another set of roots for this discipline (Lawton, 1982).
2. The growing role of the social science perspective within aging research, which began in the late 1940s of the twentieth century and set the stage for the emerging field of social and behavioral gerontology (*see* Aging, Theories of).
3. The prominent role of learning theories in psychology in the 1950s and 1960s, which underscored the importance of the environment and external stimuli in all stages of human development (*see* Human Development, Theories of).
4. The visible demographic shift toward a growing number of old and very old adults, raising issues of optimal housing and out-of-home areas for aging well.
5. The increasing importance of technology and the new media as a 'new' environment for all ages including those in their later life.

The conceptual and empirical productivity within the field grew steadily during the 1960s and 1970s (of the twentieth century). Respective research has been devoted to better understand 'aging in place' processes (how older adults manage to stay put even when faced with severe competence loss); to develop housing alternatives for older individuals; and to learn about relocation processes and outcomes and aging in institutions ever since. In addition, issues such as out-of-home mobility and more recently also the interaction with computers and virtual environments have found research attention. Also, the important health issues of mild cognitive impairment and dementia-related disorders have led to new research challenges based on the assumption that environmental design becomes particularly crucial when the cognitive capacity for person-based adaptations in later life is rather exhausted. Most recently, new areas such as the question of how climate change may affect aging have appeared as an issue of the ecology of aging.

Goals and Mission of Ecology of Aging and Role within Aging Research

Goals and Mission

The overarching aim of ecology of aging research is to describe, explain, and modify/optimize the relationship between the

aging person and his/her physical, spatial, and technological environment. With regard to description, the ecology of aging places a strong emphasis on day-to-day contexts of aging individuals, reinforcing the notion that this everyday world in natural settings deserves full attention of aging research at large. A prototypical issue is that older people spend most time in their home environment and as a consequence, housing characteristics as the major setting in which aging unfolds, has been a major focus of research in environmental gerontology from its inception.

The task of explanation basically relies on German psychologist Kurt Lewin's fundamental definition of the 'life space' as a function of the person and his/her environment ($B = f(P\ E)$). Lawton (1982) suggested an addition to the 'ecological equation' ($B = f(P\ E\ PXE)$) to account for the influence of person-environment interactions. This interaction term suggests that person-related competencies and needs operate or manifest differently in different environments and lead to dissimilar outcomes. For instance, having low- or high-mobility competence may not affect the autonomy of an individual to obtain a goal such as ascending stairs, if an escalator is also available. However, if an escalator is not available, the autonomy of the low-mobility person may be highly threatened, whereas there may be no effect on autonomy for the person with high mobility.

The focus on modification and optimization reflects the aspiration of ecology of aging research to have a substantial and direct contribution to the improvement of quality of life in old age. Prototypical is the use of ecology of aging findings in advancing evidence-driven home modifications, enriching further long-term care settings, or designing of public spaces with the goal of enhancing autonomy and well-being as people age.

With these ambitions in mind, empirical methods, such as real-life observations in natural settings, the retrospective assessment of day-to-day behaviors through the use of diaries, the reconstruction of internal representations of the environment, as well as structured questionnaires have frequently been used. Methods used to describe the environment, such as checklists for housing interiors or multidimensional evaluations of institutional settings, have also played an important role (Gitlin, 1998). More recently, tracking methods based on Global System Positioning technology or other automatized activity recording *in vivo* have found application to learn about naturally occurring mobility and space use patterns (e.g., Wahl et al., 2013).

Role of the Ecology of Aging within Aging Research

Research on the ecology of aging strives to understand the environment-related tasks that typically confront the aging individual. These tasks include preserving autonomy in everyday life despite physical and cognitive impairments through the utilization of environmental resources within (including home modifications, see Wahl et al., 2009) and outside the home, initiating the relocation process if desired or necessary and adapting to new living environments (such as a nursing home or other planned housing) after relocation. These classic research themes illustrate the fact that an interdisciplinary approach – covering disciplines such as psychology, sociology, architecture, geography, urban planning, and design – is essential for the understanding of the ecology of aging.

There are numerous implications of ecology of aging principles for models of aging well. For example, because housing figures prominently in the major day-to-day context of aging, research into the potential and constraints of the home environment addresses important issues related to preserving health and quality of life in later life. There has been and continues to be a strong desire of old and very old people to 'age in place,' remaining in their familiar home environment or an environment of their choice for as long as possible. This desire may ultimately reflect an optimization strategy critical to late life; it affords continuity and control over important aspects of daily life, including routines, self-care, and other potentially meaningful and self-defining activities. In sum, ecology of aging principles may be particularly critical to understanding the 'good life' in old age (Lawton, 1983).

Major Themes, Theoretical Approaches, and Findings of the Ecology of Aging

The in-depth understanding of person-environment processes and outcomes has so far not been achieved by any one major theory; rather a multitude of conceptual approaches that augment and build on each other in a pluralistic manner have been suggested over the years since the inception of ecology of aging research in the 1970s.

Objective Approaches to Person-Environment Relations

The Competence-Press Model (Lawton, 1982) provides a broad, overarching framework allowing different types and levels of competence such as sensory loss, physical mobility loss, or cognitive decline and environmental factors including housing standards, neighborhood conditions, or public transport to be considered. The fundamental assumption is that for each aging person there is an optimal combination of (still) available competence and environmental circumstances leading to the relative highest possible behavioral and emotional functioning for that person. The model also suggests that it is at the lower levels of competence that older people become the most susceptible to their environment such that low competence in conjunction with high 'environmental press' negatively affects an individual's autonomy, effect, and well-being. The competence-environmental press framework continues to provide the basic mechanism of person-environment relations as people age and has been supported by a considerable body of empirical research. For example, research of the impact of physical distances on social interaction patterns of elders in institutional settings shows that longer distances undermine social relations, thus highlighting the 'environmental docility' as people age. Furthermore, the Competence-Press Model has become a major driver in the practical world of designing and optimizing environments for older adults.

Besides putting emphasis on competence as is done in the Competence-Press Model, other conceptions underscore the role of person-environment fit and motivational forces in person-environment relations (see also Lawton, 1982). The basic

assumption is that the lack between given needs and given environmental options to fulfil these needs is linked with lowered behavioral functioning and well-being. Empirical support for this assumption has been reported by studies conducted in institutional settings as well as private home environments. For example, remaining autonomy in visually impaired elders was found to depend on how much the physical layout of home environments adds to the compensation of the vision loss. Furthermore, a distinction between an older person's basic versus higher-order needs has been suggested. Basic needs are related to basic issues of maintaining competence (e.g., maintaining independent self-care), while higher-order needs address issues such as privacy and affiliation. While person-environment misfit in the basic need domain predominantly results in reduced behavioral autonomy, misfit in the higher-order need realm predominantly may also undermine emotional well-being and mental health.

The Person-Environment Stress Model (see also Lawton, 1982) argues that objective environmental conditions such as lack of accessibility, privacy, or control in one's environment may provide the source for stress experiences. For instance, aging individuals may feel a psychological threat, apathy, reduced well-being, or depression as a consequence of such stress experience. This model can be applied to family care giving as well. For example, difficult to manage dementia-related behaviors and lack of control over daily routines reflect the objective environmental conditions that typically confront families of persons with dementia. These environmental stressors over and above subjective appraisals of the care situation may affect a caregiver and result in significant stress, anxiety, or depression.

Finally, relocation may be seen as the most radical alteration in person-place relations. The understanding of residential decisions and their outcomes in old age has attracted the ecology of aging from early on in the development of the field. Litwak and Longino (1987) suggested a distinction between first, second, and third moves by relying on the assumption of a substantial association between chronological age and type and motivation of move. Whereas 'first moves' often take place early in the aging process, that is, close to retirement, and are usually prompted by the amenities associated with the desired place of residence, 'second moves,' appearing in the 70s and early 80s of age, are predominantly characterized by moving back to the place of origin, reflecting a higher need for support and proximity to kinship. 'Third moves' are often relocations to institutions due to frailties that are not compensable by family resources in very old age. As has been found in more recent research, relocation is driven in current cohorts of older people by a variety of motivations, among which higher-order needs such as access to participation in social, cultural, and educational opportunities appear to become increasingly important. A primary example is the so-called Sunbelt Movers, that is, the move of mostly 'young old' people to places better serving their needs in terms of climatic conditions and/or surrounding communities as found in 'Sun Cities.'

Subjective Approaches to Person-Environment Relations

The classic approach addressing the cognitive-affective relation to the physical environment is reflected in the construct of housing satisfaction. As has consistently been found, older adults, both healthy and frail, tend to score high in measures related to this construct, regardless of their objective home and neighborhood conditions. This has been coined the 'housing satisfaction paradox.'

Besides residential satisfaction, a widely acknowledged approach suggested by Rowles (1983) has focused on the many faces of what he has coined 'insideness.' According to Rowles, different types of insideness that speak to the transition of 'spaces into places' can be empirically derived. Whereas 'social insideness' arises from everyday social exchanges over long periods of time, 'physical insideness' is characterized by familiarities and routines within given settings such as the home environment. A third element of insideness has been labeled 'autobiographical insideness,' that is, places carry a rich collection of memories and thus support the aging individual's sense of place identity. Empirical research has also shown that physical insideness is particularly important for aging individuals with chronically disabling conditions.

Rubinstein's conception of the 'meaning of home' (see Oswald and Wahl, 2005) relies on the assumption that the active management of the environment in itself represents a major source of well-being as people age, especially for those who are frail or living alone. Rubinstein identifies three classes of psychosocial processes that give meaning to the home environment, namely 'social-centered,' ordering of the home environment based on a person's version of sociocultural rules for domestic order; 'person-centered,' expression of one's life course in features of the home; and 'body-centered' processes, the ongoing relationship of the body to the environmental features that surround it. Furthermore, 'place attachment' has been defined as reflecting feelings about a geographic location and emotional binding of a person to places. As has been empirically found, place attachment seems to steadily grow across the life course, reaching its culminating point in very old age.

Role of Out-of-Home Environments for Aging Well

As Wahl et al. (2007) argued, the presence of service facilities for daily necessities and appropriate health care nearby, areas of recreation and stimulation, cultural facilities, natural characteristics, and feeling safe and secure in the area, are all essential factors linked to autonomy and personal well-being. Regional conditions – especially those relating to the degree of urbanization and distances between places of residence – can also affect the frequency and nature of contacts with important reference persons and participation in social activities that are regarded as crucial elements for the quality of life of older adults. Older people in rural areas live generally less far away from their most important confidants than older urbanites, while the transportation times needed in, for example, large urban areas increase the difficulties of maintaining social relationships. Such structural characteristics refer to the significance of out-of-home mobility as an increasingly important precondition for maintaining an independent lifestyle in later life and keeping up social relationships and the connection with one's community. Improvements in transport technologies, accompanied by changes in the constitution and nature of urban and rural

settlements, have resulted in a growing dispersal of travel origins and destinations and the necessity of bridging the widening gap between functional areas. Apart from these functional aspects of getting places, mobility can be performed for its own sake. Moreover, in modern society, mobility is associated with highly valued societal goals such as freedom, autonomy, and flexibility (*see* Retirement and Encore Adulthood: The New Later Life Course).

Technological Environments and Aging – Some Considerations

Rogers and Fisk (2010) have argued how important it is for older adults' use of technology to match psychological needs with design characteristics. They also refer to the Competence-Environment Press Model (Lawton, 1982) according to which successful performance is depending on the demands imposed by the environment in relation to the capabilities of the individual. Lindenberger et al. (2008) suggest that the interaction between the older person and technology should be seen against three fundamental principles: (1) net resource release, or marginal resource benefit; (2) person specificity; and (3) proximal versus distal frames of evaluation considering constraints as well as capabilities of aging individuals. The first principle of 'net resource release' states that the use of technology is only adaptive if the operation costs (resource investments) are lower than the pay-offs regarding the cognitive resources that are released. For example, using a complex videophone system initially requires substantial resource investments to understand the instructions, resulting in a low resource balance regarding this device. When developing and evaluating assistive technology, objective and subjective assessments of the resource balance should be taken into account. Improvements in the resource balance caused by using the technological device should be of significant amount – at least in the long run. To enable such benefits it is essential that technological and psychological knowledge is integrated. The second principle of 'person specificity' points to the need of adaptation to the specific habits, abilities, and preferences of the potential users. Besides the general importance of taking seriously the pronounced heterogeneity of the older population, it seems crucial to introduce the potentially helpful role of technology early in the disablement process, in particular before the onset of severe cognitive impairment. By this means, the older user may be able to adapt easier to the technology in the longer run, even if cognitive decline happens at a later point in time, and there still remains room for precise adjustment on the part of the device concerning the user's specific competences or preferences. The third principle of 'proximal versus distal frames of evaluation' focuses on long-term benefits, considers risks regarding the entire lifespan, and takes into account possible historical changes. Depending on the observation period, the evaluation may provoke different results. Following the three principles of Lindenberger et al.'s (2008) framework, the relation between support and challenge of technology can be improved with positive implications for everyday performance, participation, and well-being. It is obvious that to use this opportunity in its full potential, close interdisciplinary collaboration between psychologists, engineers, computer scientists, and geriatricians is needed.

Approaching Person-Environment Relations on the Macrolevel of Analysis

The aforementioned approaches predominantly consider person-environment interactions on the microlevel of analysis; that is, the focus is on obtaining an in-depth understanding of the role of the immediate environment within which people age. However, as Bronfenbrenner's (1979) ecological theory of human development and other social science approaches suggest, in targeting person-environment relations, the micro-environmental level is undoubtedly influenced and shaped as well by macrolevel environmental contexts including the neighborhood at large, housing policies, economic standards, cultural values and beliefs, and social and long-term care service provision and policies. These factors all form the environmental context of aging with varying immediate and distal impacts on everyday life of people as they age. As has been found, the quality of neighborhood settings may strongly affect the physical range and timing of out-of-home activities as people age. An important consideration is the life course perspective. It could well be that persons initially live in high-quality neighborhoods that subsequently decline over time, placing people in the later years of their life at a disadvantage. Another classic research question is the urban-rural distinction and how this affects aging. For example, use of the outside environment may depend upon public transportation possibilities and these may be more underdeveloped in rural than urban regions. On the other hand, the macrolevel perspective also considers the diversity in cultural norms, and it could well be that disadvantages in person-environment options in rural areas are compensated for because of stronger intergenerational and higher prevalence of cohabitation of older and younger family members. Still one level up, the consideration of person-environment interrelations is worth considering across countries, that is, as a cross-cultural research challenge. For example, the definition of barrier-free environments and respective legislative norms and regulations probably depend on the economic situation as well as on different cultural conceptions of autonomy and the role of physical environments compared to social environments such as the family system.

Toward Integrative Views

To expand important perspectives in the field of the ecology of aging and link them more closely with developmental models of aging well, a framework as depicted in **Figure 1** may be helpful (Wahl et al., 2012). At the core of this framework is the assumption that two processes, experience-driven belonging and behavior-driven agency, help to better understand and integrate person-environment interchanges as people age. 'Belonging' reflects a sense of positive connection with other people and the environment, while 'agency' refers to the process of becoming a change agent in one's own life by means of intentional and proactive behaviors.

We argue that adapting these constructs to the person-environment sphere is worthwhile, as they are particularly useful for understanding the role of environment for aging well. Going further, the model assumes that person-environment resources are essential to both belonging and agency. Personal resources, including functional abilities,

Figure 1 Conceptual framework: interplay of belonging and agency, aging well, and the environment. Reproduced from Wahl, H.-W., Iwarsson, S., Oswald, F., 2012. Aging well and the environment: toward an integrative model and research agenda for the future. The Gerontologist 52 (3), 308. http://dx.doi.org/10.1093/geront/gnr154.

cognitive and affective functioning, and personality traits, may gain or lose importance in specific environmental configurations. Similarly, environmental resources, including barrier-free housing or innovative housing solutions, are utilized differently across persons. Our model also posits that the interaction of belonging and agency unfolds within a life course perspective, with the processes of belonging increasing in importance as people enter old and particularly advanced old age, while the relevance of processes of agency decreases. Figure 1 also points to the need to pay serious attention to historical, cohort-related, and cultural context. Historical changes relevant to aging well can be traced to changes in aging individuals' relations with the environment. For example, the impact of the environment on aging well has probably increased as new housing solutions for older adults, such as assisted living or intergenerational arrangements, and new housing options for persons with dementia have replaced traditional built environments. Finally, aging well is seen as maintaining the highest autonomy, well-being, and preservation of one's self and identity as possible, even in the face of severe competence loss.

Future Considerations

Future research on the ecology of aging is faced with at least four challenges:

1. Theoretical challenges: Much of the theoretical substance in this field was developed in the 1960s and 1970s (of the twentieth century). One particularly fruitful theoretical avenue may be to strengthen the links between ecological theories and promising conceptual approaches within psychological gerontology. A prototypical example is the lifespan theory of control (Heckhausen et al., 2010), which focuses, on a wider scale, also on person-environment relations and their alterations across the human life span.
2. Methodological challenges: Although the use of naturalistic methods such as observations and online data-collection strategies (e.g., by using i-pads in everyday life situations) have proven themselves to be indispensable tools in research on the ecology of aging – as well as for gerontology in general – the methods used are rarely comparable. One of the most important methodological challenges is creating an established set of instruments able to robustly assess the older adults' interaction with the physical, spatial, and technological environment. It may also become very fruitful to better link ecology of aging issues with the neurosciences in the future (*see* Brain Aging (Normal): Behavioral, Cognitive, and Personality Consequences). For example, it is currently mostly unknown, whether different housing solutions may also affect differently on the aging brain.
3. Application and societal challenges: Due to the rapidly growing number of older adults and particularly 'old-old' adults beyond the age of 85 years, one of the main challenges of today's and tomorrow's societies is providing care for the demented older adults. Research on the ecology of aging must be strongly committed to planning and evaluating supportive environments for these people. In addition, the growing impact of information and communication technology such as the Internet, the use of high-tech solutions in housing and in public community life, as well as the rapidly growing role of technology in geriatric care have given rise to a whole range of new environmental characteristics. Research on the ecology of aging will thus continue to encounter new challenges in the future.

Abstract

Until the mid-1970s, the prominent approach in organization and management theory emphasized adaptive change in organizations. Since then, an approach to studying organizational change that places more emphasis on environmental selection processes has become increasingly influential. The stream of research on ecological perspectives of organizational change has generated tremendous excitement, controversy and debate in the community of organization theory scholars.

Inspired by the question '*why are there so many kinds of organizations?*' (Hannan and Freeman, 1977), organizational ecology aims to explain how social and economic conditions affect the relative abundance and diversity of organizations and to account for their changing composition over time. Ecological research typically begins with three observations: (1) diversity is a property of aggregates of organizations, (2) organizations' members often have difficulty devising and executing organizational changes fast enough to meet the changing demands of uncertain environments, and (3) the community of organizations is unstable – organizations come and go continually. Consequently, contrasting adaptation approaches (*see* Structural Contingency Theory) emphasizing individual organizations' cumulative strategic changes, ecological analyses formulate organizational change and variability at the population level, highlighting the creation of new and the demise of old organizations and populations.

Historically, research has focused primarily on analyses of the influence of demographic and ecological processes on rates of organizational founding and failure. The focus of research has changed over time, however, as attention turns to processes of organizational change. As Hannan and Freeman (1977: p. 930) pointed out, a full treatment of organization–environment relations must cover both adaptation and selection. Researchers have embarked on development of an integrated perspective that sees processes of adaptation and selection as complementary and interacting. The emerging view takes seriously the occurrence of selection processes and combines it with the systematic study of organization-level changes that may, under certain conditions, be adaptive.

Demographic Processes

Organizational Founding

Although organizational founding is an important theme in ecological research, in large part, foundings are treated as identical additions to homogenous populations; the characteristics of new organizations, which define their domains, have not been of central interest. Initially, researchers avoided this issue by treating the population as the unit experiencing the foundings. The problem with this approach is that variations in social and economic conditions across a population's environment will produce differences in founding rates, which, if not properly accounted for, will result in specification bias.

Progress has been made by specifying more fine-grained subpopulations into which organizations are differentially founded. A variety of criteria have been employed, including legal form (Baum and Oliver, 1996), core technology (Barnett, 1990), customer base (Baum and Singh, 1994), and geographic location (Cattani et al., 2003). In this approach, studying founding involves specifying potential subpopulations and examining differences in the rate at which new entrants arrive. One limitation is that subpopulation definitions can be artificial and arbitrary; another is that it affords accounts only of foundings into organizational niches that were actually filled.

Several approaches have appeared that address these concerns. Each begins with the observation that variation in social, institutional, and economic conditions across regions can produce differences in founding rates of particular organizational forms. Lomi (1995) proposes a model of location dependence in organizational founding in which corrections for unobserved heterogeneity are estimated directly from data. Baum and Haveman (1997) complement ecological analyses that ask when a founding will occur – by any kind of organization within a population, in any location in that population's niche – by taking organizational foundings as given and asking instead, '*what kind* of organization is founded and *where*?' Their concern is with new organizations' similarity to (difference from) incumbent organizations: given that a new organization appears how similar it is to neighbors? Sorenson and colleagues (Barnett and Sorenson, 2002; Stuart and Sorenson, 2003) make use of continuous measures of the distance between fine-grained geographic units (zip codes), permitting effects of particular variations in social and economic conditions on the founding rate to be estimated directly.

These and related studies have refocused organizational ecologists from an emphasis on temporal heterogeneity in organizational founding to less studied issues of spatial heterogeneity and location dependence. The approaches to the dynamics of spatial and location choice they advance make it possible to subject theoretical predictions from spatial economics and organizational sociology to empirical testing, improving our knowledge of key entrepreneurial decisions and processes, and the tendency for firms to cluster (or not) in a resource space (*see* Entrepreneurship and Economic Growth).

Age and Size Dependence

The relationship between organizational aging and failure is a central demographic inquiry. The predominant view was initially the liability of newness (Stinchcombe, 1965), which assumes that because they have to learn new social roles,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.73111-4

create new organizational routines, and lack endorsements and exchange relationships, young organizations will have higher failure rates. A complementary idea is that selection processes favor structurally inert organizations capable of demonstrating reliability and accountability, which requires high reproducibility. As reproducibility is achieved through the routinization that comes with age, older organizations should be less likely to fail (Hannan and Freeman, 1984).

A related line of research examines how organizational size affects failure. The high failure rate of small organizations results from several liabilities of smallness, including problems with recruiting and training employees, raising capital, and costs of regulatory compliance. As organizations grow, they increasingly emphasize predictability, formalization, and control, improving their reliability and accountability, and lowering their susceptibility to failure. The significance of 'smallness' stems in part from its relation to 'newness': as new organizations tend to be small, if small organizations exhibit higher failure rates, empirical evidence of a liability of newness may reflect specification error. Indeed, although early studies consistently support a liability of newness, subsequent studies controlling for time-varying size typically do not, prompting formulation of alternative views on age dependence.

The liability of adolescence (Fichman and Levinthal, 1991) predicts a ∩-shaped relationship between age and failure. New organizations begin with a stock of assets (e.g., goodwill, commitment, resources) that buffer them during an initial 'honeymoon' period – even if early outcomes are unfavorable. The larger the initial stock, the longer the buffering. As initial endowments are depleted, however, organizations unable to meet ongoing resource needs, for example, because they are unable to establish effective routines or exchange relations, may fail.

Liabilities of newness and adolescence yield divergent predictions for new organizations, but because processes underlying these models occur at an early age, they do not apply to older organizations. The liability of aging (Barron et al., 1994), which identifies processes affecting older organizations, begins with another insight from Stinchcombe (1965): organizations are imprinted by their founding environment. Over time, bounded rationality and structural inertia make it difficult for organizations to remain aligned with shifting environmental demands. Encountering a series of environmental shifts may thus expose aging organizations to a risk of obsolescence. Aging may also bring about senescence, a buildup of internal politics and precedent that impede action. Obsolescence and senescence pose separate risks. Senescence is a direct effect of aging; obsolescence a result of environmental change.

Among studies controlling for time-varying size, empirical estimates are mixed (Baum and Shipilov, 2006). The divergent results might reflect the effect of age varying with that of size, masking 'true' age effects or alternatively variation in age dependence across populations. To resolve such questions, research must test alternative models' mediating variables directly rather than using age as a proxy for all underlying constructs (Baum, 1996). Such an approach treats the alternatives as complementary rather than (falsely) as competing models (*see* Development: Organizational).

Organizational Change

Research on organizational change typically concentrates on content: a change to a more (less) advantageous arrangement is considered adaptive (detrimental) (*see* Organizational Change; Development: Organizational). Complementing this focus, ecological research emphasizes the change process, raising two basic questions.

How Changeable Are Organizations?

The 'structure' in structural inertia theory refers to core organizational features (goals, authority structures, technical core, and market strategy) related to mobilizing scarce resources for beginning an organization and then maintaining resource flows (Hannan and Freeman, 1984). Peripheral features buffer an organization's core from uncertainty. Core features exhibit greater inertia than peripheral features; but the claim is not that core features do not change, only that they change slower than the environment. Hannan et al. (2003) portray structural inertia as a cascade of organizational changes following an initial change. The time spent reorganizing and associated opportunity costs, which increase with the complexity and sluggishness of the change, generate structural inertia. Ecology's inertia is thus a relative concept; adaptation and learning are not excluded, just not taken-for-granted. Nor does structural inertia theory remove individuals from responsibility for their organization's survival. Indeed, it implies that the capacity of individuals to change organizations successfully is of utmost importance.

Although not included in structural inertia theory, a complete understanding of change processes also requires consideration of organizations' change histories (Amburgey et al., 1993). The more experienced an organization becomes with a particular change, the more likely it is to repeat it. If the change becomes linked with success in decision-makers' minds – rightly or wrongly – repetition is more likely still. The change process may thus itself become routinized, creating the tendency to maintain direction and emphasis of prior actions in current behavior. To reconcile such 'momentum' with commonly observed periods of organizational inactivity, Amburgey et al. contend that local search reinforces momentum immediately after a change occurs, but it subsequently declines.

Empirical support for structural inertia theory remains equivocal; support for momentum is stronger (Baum and Shipilov, 2006). Overall, research indicates that, while constrained by inertia and momentum, organizations often initiate change in response to environmental shifts. Of course, inertia and momentum are not necessarily harmful: in addition to promoting reliability and accountability, in an uncertain environment they prevent organizations from responding too quickly and frequently to environmental change. Ultimately, whether inertia and momentum are adaptive depends on the hazardousness of change.

Is Change Beneficial?

According to structural inertia theory, core change disrupts established routines and exchange relations, and undermines organizational legitimacy by impairing reliability and accountability. Organizations may thus fail as a result of their

attempts to survive – even attempts that might ultimately have proved beneficial. Because their structures, routines, and relationships are more institutionalized, older organizations are especially prone to experience disruption following core change. In contrast, large organizations can buffer themselves from disruption by, for example, maintaining both old and new routines during transition or overcoming resource deprivations accompanying the change. If an organization survives the short-run disruption, its failure rate is predicted to decline as reliability, exchange relations, and legitimacy are reestablished over time. Only if the rate of decline is faster than before the change, however, will the organization ultimately benefit from taking the short-term risk.

Empirical studies indicate that while core change is not necessarily disruptive in the short run, neither do organizations necessarily improve their survival chances in the long run (Baum and Shipilov, 2006). Two research design problems, however, appear to produce systematic underestimates of the hazardousness of change. First, the annual data typically used may not detect the deadliest core changes – those quickly proving fatal. Second, because organizations founded before a study period are not observed when they are youngest, smallest, and most vulnerable to change, their inclusion likely biases downward the risk of change.

Organizational Learning

Complementing the growing interest in organizational change and its consequences is an emerging stream of research exploring the effects of organizations' experiential learning on their survival chances (*see* Learning: Organizational).

The idea that experiential learning improves efficiency is not inconsistent with the possibility that, simultaneously, overall organizational effectiveness decreases if the organization does not adjust to new demands (March 1991). Consistent with this observation, Baum and Ingram (1998) find support for a U-shaped effect of 'operating experience' (i.e., accumulated unit operating years) on organizational failure rates. Initially, the rate of failure decreases with experience as the organization moves down the learning curve for its favored set of routines. Eventually, however, accumulating experience causes the organization to become less able to adapt and, as the demands of the environment change, more likely to fail. In complementary work, Barnett and Hansen (1996) study 'competitive experience' (i.e., aggregate number of years an organization faced competition from rival organizations), differentiating between recent and distant competitive experience, expecting (and finding) that recent competitive experience would be beneficial, while older competitive experience would be detrimental.

Ecological studies of organizational learning advance our understanding of the role of experiential processes in organizational adaptation and selection. Experiential learning is a double-edged sword – it can enhance organizational survival chances while at the same time hindering adaptation; it can strengthen competitive abilities while at the same time making competition harder. Moreover, this research contributes to answering the question of how aging influences organizational failure by modeling more directly experiential learning constructs invoked by liability of newness and aging hypotheses.

Ecological Processes

Niche-Width Dynamics

Niche-width theory (Hannan and Freeman, 1977) focuses on two aspects of environmental change – variability and grain – to explain the differential survival of specialists, those who possess few slack resources and concentrate on a narrow range of customers, and generalists, those who attempt to appeal to the mass market and exhibit tolerance for more varied environments. Variability refers to the size-related environmental fluctuations over time. Grain refers to the patchiness of these fluctuations, with fine-grained fluctuations being frequent and coarse-grained infrequent. The key prediction is that in fine-grained environments, with large-magnitude fluctuations, specialists ride out the fluctuations, outcompeting generalists who are unable to respond quickly enough to operate efficiently. Niche-width theory thus challenges the classic prediction that uncertain environments always favor generalists that spread their risk (*see* Structural Contingency Theory).

In contrast to niche-width theory, which implies an optimal strategy for each population, Carroll (1985) proposes that, in environments characterized by economies of scale, competition among generalists to occupy the center of the market frees peripheral resources that can be used by specialists; a process he refers to as resource partitioning. His model predicts that in concentrated markets specialists can exploit more resources without engaging in direct competition with generalists, and by implication, while increasing market concentration increases the failure of generalists, it lowers the failure of specialists.

Although the specialist–generalist distinction is common in ecological research, tests of niche-width theory are scarce, and resource-partitioning studies do not typically contrast niche-width and resource-partitioning predictions. Yet, there is a conflict between these two theories. They offer distinct views of specialism and generalism and the tradeoff between organizational survival and niche width. The theories also focus on different kinds of niches, niche-width theory emphasizing *fundamental niches* (i.e., the set of environments in which an organization can survive in the absence of competition), and resource-partitioning theory emphasizing *realized niches* (i.e., the subset of the fundamental niche in which an organization can survive in the presence of competitors). It is thus unclear whether the two theories differ fundamentally or can be integrated into a unified theory. However, there have been early efforts to link the two theories (Dobrev et al., 2001) by combining niche-width theory's emphasis on environmental dynamics with resource partitioning's emphasis on scale advantages.

Population Dynamics and Density Dependence

Ecological research on founding and failure has given considerable attention to endogenous population dynamics and density dependence. Prior population dynamics – patterns of founding and failure – shape current founding rates (Delacroix and Carroll, 1983). Initially, prior foundings signal opportunity to entrepreneurs, encouraging founding. But as foundings increase, resource competition increases, discouraging founding. Prior failures have

analogous effects. At first, failures release resources for entrepreneurs. But further failures signal a hostile environment, discouraging founding. Resources freed by prior failures may also enhance the viability of established organizations, lowering failures (Carroll and Delacroix, 1982). Density-dependent explanations for founding and failure are similar, though not identical. Initial increases in the number of organizations can increase the legitimacy of a population, enhancing the capacity of its members to acquire resources. However, as a population continues to grow, competition with others for scarce common resources intensifies. Combined, the effects of legitimacy and competition imply an inverted U, that is, ∩-shaped relationship between density and founding and a U-shaped relationship between density and failure (Hannan and Carroll, 1992).

Studies of numerous organizational populations provide empirical support for density-dependent founding and failure; population dynamics findings are mixed and, when modeled together with population density weaker still (Baum and Shipilov, 2006). One explanation for the dominance of density dependence over population dynamics is the systematic character of density relative to the changes in density produced by founding and failure. A related account is the sensitivity of rate dependence to outliers. Regardless, population dynamics has been largely abandoned in recent research.

Despite strong support for density dependence, it has received critical attention for its (1) proposed integration of ecological and institutional perspectives, (2) assumption that each organization influences and is influenced by competition equally, (3) inability to explain the concentration common to older populations, and (4) inattention to problems of unobserved heterogeneity. Several innovative elaborations, respecifications, and measures, summarized in **Table 1**, have been advanced to address these questions.

Population Learning

Complementing the growing ecological interest in organizational learning is an emerging line of research exploring how organizations' collective experiences lay the foundation for population learning. Although organizational learning tends to focus on refining existing routines, at the population level diverse goals and incentives foster the proliferation of new ideas and routines. A population can thus encompass a great deal of variety without violating internal or external standards of consistency and reliability, and therefore more varied experience than an organization. Moreover, by observing their population, organizations can potentially learn a multiplicity of routines employed by other organizations. An organization's own experience is thus not the only opportunity for learning; organizations may also learn from the operating and competitive experience of others in their population.

Ingram and Baum (1997), for example, study the effects of population operating experience (i.e., unit operating experience of other organizations) accumulated both prior to and since an organization's founding. Controlling for organizational operating experience, both types of population operating experience significantly lowered organizational failure rates. Baum and Ingram (1998) attempted to replicate these findings and did so for population operating experience at founding, but not accumulated since founding.

Ingram and Baum (1997) also observed that organizational outcomes also depended on competitors' actions. Operating

Table 1 Elaborations of the density dependence model

Model	*Critiques*[a]	*Elaboration*	*Key references*
Density delay	3	Incorporates imprinting effect of density at founding	Hannan and Carroll (1992)
Mass dependence	2,3	Weights each organization's competitive effect by its size	Barnett and Amburgey (1990)
Multiform models	2	Estimates intrapopulation microstructures and interpopulation (community) macrostructures	Barnett (1990)
Level of analysis	2,3	Estimates variation in density dependence across levels of geographic aggregation (city, state, region, nation)	Hannan et al. (1995)
Institutional embeddedness	1,4	Estimates population legitimation with relational density (endorsements by powerful actors and organizations)	Baum and Oliver (1992)
Localized competition	2,3,4	Weights competitive effects of organizations on each other by their proximity (size, price, location)	Baum and Haveman (1997)
Organizational niche overlap	1,2,4	Disaggregates population density for each organization based on resource (non)overlaps with other organizations	Baum and Singh (1994)
Location dependence	2,4	Incorporates information on spatial structure of organizational populations	Lomi (1995)
Time variation	1,2,3	Estimates variation in density dependence as a population ages	Baum (1995)
Dynamic selection	2,3,4	Incorporates variation in the strength competitive processes as a population ages	Baum (1995)
Competitive intensity	2,3,4	Weights each organization's competitive strength by its age	Barnett (1997)
Scale-based competition	2,3,4	Benefits of size are a function of positional differences with larger, rather than all other organizations	Dobrev and Carroll (2003)

[a]Critiques. 1 = Proposed integration of ecological and institutional perspectives. 2 = Assumption that each organization influences and is influenced by competition equally. 3 = Inability to explain concentration common to older populations. 4 = Inattention to problems of unobserved heterogeneity.

experience can generate part of what is necessary for a model of competitors, but it is necessary to observe competitive outcomes. Measuring population competitive experience based on the number of failures observed by organizations, and controlling for organizational and population operating experience, they found that population competitive experience accumulated since an organization's founding lowered failure rates, but population competitive experience at its time of entry had no effect on failure.

These and related findings (e.g., Barnett, 1997; Sorenson, 2000) highlight the heterogeneity of organizational forms across time over successive cohorts of organizations. Population learning extends traditional ecological analyses, which emphasize that organizational change and variability reflect primarily inert organizations replacing each other, but not the implications of vicarious learning by new entrants and established organizations.

Abstract

E-learning is the use of digital tools for learning. Learning management systems and distance education are among the most prevalent tools. However, hybrid experiences and collaborations are changing the E-learning landscape. Recent developments include the advent of social networking and online learning communities, the ubiquitous presence of smart phones, and an increased recognition of the potential for computer games to transform learning. Other important developments include advances in Intelligent Tutoring Systems, the free Open Educational Resources movement, and the creation of immersive environments allowing users to engage with virtual environments and to digitally augment their experience of the real world.

E-learning can be defined as the use of electronic tools to support teaching and learning. E-learning can be experienced in many formats. These formats and delivery methods include stand-alone computers, the Internet, and satellites with learning materials provided by an instructor, an animated intelligent agent, or through media such as text, images, sounds, and video. E-learning can take place in practically any location including: classrooms, homes, and in remote field locations. Additionally, E-learning tools can be used at the learner's own pace. Most people with adequate resources and some understanding of technology can engage in E-learning by one means or another. E-learning has been used in public and private primary, secondary, and postsecondary schools throughout the United States and around the world. Additionally, homeschoolers, government agencies, militaries, and private businesses have utilized E-learning as learning and training tools.

'Traditional' E-Learning and E-Communication

Most colleges and universities in the world have made significant use of E-learning technologies since before the turn of the century (Wolfe, 2001a). In recent years for-profit institutions such as the University of Phoenix have become familiar fixtures on the higher education landscape. For example, the University of Phoenix offers 40 complete online Bachelors Degrees ranging from a Bachelor of Arts in English to an RN to Bachelor of Science in Nursing (University of Phoenix, 2012). The most prevalent tools for these applications are learning management systems and distance education platforms.

Learning Management System

Learning management systems are software applications used by educational systems as an online method to give students access to course content, and for educators to track, develop, and integrate relevant course information (Ellis, 2009). With only a computer and Internet connection, students can access relevant course content, grades, email, and class discussion boards or forums (Ellis, 2009). Online courses use learning management systems as their main information delivery method (Ellis, 2009). A limitation of these systems is that because the system itself does not teach, learning from the system cannot occur (Ellis, 2009). Learning management systems are simply online tools that can be used as a method to deliver information.

Blackboard Learning System

One of the most popular learning management systems was developed in 1997, it is called Blackboard Learning System (Bradford et al., 2007). Blackboard, like most learning management systems, offers a way for students and educators to communicate and deliver content (Bradford et al., 2007). Communication features include: announcements that all students in a course can read, an online chat feature, discussion boards, and email (Bradford et al., 2007). Content in the Blackboard system includes: course content such as articles or assignments, calendars to remind student about due dates, learning modules mostly utilized by online only courses, assessments such as quizzes and exams, assignments, a grade book, and a media library (Bradford et al., 2007). While largely used by learning institutions, Blackboard has also been used by corporations and government organizations. Blackboard also has other product platforms including: Blackboard Collaborate, Blackboard Mobile, Blackboard Connect, Blackboard Transact, and Blackboard Analytics (Bradford et al., 2007).

Sakai

Another common learning management system is called Sakai. Developed in 2005, this open source educational software is offered as a free community resource under the Educational Community License and has over 350 educational organizations that use the system. Sakai's collaboration tools include announcements, dropbox, email and archives, resources, chat rooms, forums, message centers, news/RSS, a poll tool, presentation, profile of site participants, a search, and a schedule. Institutions using open source software, rather than proprietary products have the ability to tailor the learning management system to their own particular needs.

Distance Learning

Distance education emphasizes delivering education via technology to students who are not able to be physically present in a traditional classroom. There are full distance learning courses, where teacher and student will never meet and all education is

carried out over the Internet, and courses where occasionally students and teachers might meet up to do such things as take an exam. Students also have the option of enrolling full time in distance learning classes or only taking a few classes toward their degree. There are many types of institutions that offer distance learning classes including: nonprofit, for-profit, accredited, unaccredited, and even doctoral programs.

Synchronous and asynchronous learning methods are both used in distance education. With synchronous learning, a class will 'meet' at a predetermined time via web conferencing, videoconferencing, live streaming video, television via direct-broadcast satellite, telephone, and web-based Voice-over-Internet Protocol (VoIP; Burns, 2011). Synchronous classes are carried out as if it were traditional classrooms, only the teacher and the students are not be in the same room (Burns, 2011). With the asynchronous learning method, students can access class materials whenever they so choose (Burns, 2011). Teachers typically post materials on the classes learning management system site for students to access. Students can then download and upload material, participate in message board forums, email other students or the teacher, and access print and audio material (Burns, 2011).

Open Educational Resources

Open Educational Resources are free online media and documents that are used for teaching and learning. These resources are delivered via platforms that allow creation and delivery of educational materials including college courses and materials (Caswell et al., 2008). Students taking courses in this manner do not pay tuition or receive credit, nor are degrees awarded. These resources are funded by universities and donations. The Open Educational Resources movement, whose goal is to foster collaboration, knowledge, and education across the globe, is one source of support for open educational resources (Caswell et al., 2008). Open Education has drawn the interest of journalists in recent years, in part because some of the most respected universities in the world have become active in the massive online open courses movement.

In 2001 the MIT initiative, called MIT OpenCourseWare, was the first to offer open educational resources, sparking the Open Educational Resources movement (Caswell et al., 2008). MIT OpenCourseWare started offering their entire course catalog online in 2002 for no cost. Currently MIT has over 2080 courses available online; the material available varies from reading lists, discussion topics, homework problems and exams, lecture notes, and streaming video of lectures. International members of OpencourseWare include: Brazil, Mexico, China, India, Japan, Germany, and the Netherlands (Caswell et al., 2008)

The Stanford Engineering Everywhere (SEE) initiative, started by Stanford University, is a program that offers several online courses taught by Stanford professors free of charge. These classes have instructional videos, reading lists, assignments, class lectures, and are offered globally (Van Orsdel, 2012). As of 2012, there are 10 courses being offered from Stanford's School of Engineering (Van Orsdel, 2012). The SEE encourages students to use the course material for any purpose that fits their needs. Additionally, in an attempt to foster collaboration the SEE encourages educators to use their lectures, handouts, notes, or tests in their own classrooms (Van Orsdel, 2012).

There are currently over 200 institutions around the world that are part of the OpenCourseWare Consortium. These include Europe's Learning Resource Exchange for schools, Washington State's Open Course Library Project, California Learning Resources Network, the China Open Resources for Education, OpenCourseWare in Japan, and numerous initiatives to digitize textbooks for all grade levels by countries such as Bangladesh, Uruguay, South Korea, South Africa, and Saudi Arabia (Caswell et al., 2008).

There are also open educational resources for grades K-12. Curriki is nonprofit organization that provides an Internet site for open source curriculum for primary school students that allows universal access to relevant curriculum and other instructional materials (Kurshan, 2008). The Curriki community provides its members educational materials such as digital textbooks, learning videos, and other interactive resources that are peer-reviewed as adhering to traditional educational standards (Kurshan, 2008). The active leadership of highly respected institutions, and peer review, have held in check growing perceptions that E-learning is becoming a second rate alternative to more expensive traditional colleges and universities.

Hybrids, Collaborations, and Partnerships

E-learning is both transforming and challenging the organizational infrastructure of education. Organizations such as the Serious Games Initiative at the Woodrow Wilson Center for International Scholars and the iCampus initiative at MIT have brought together educators, multi-media experts, programmers, game makers, policy makers, and scientists in surprising and potentially fruitful configurations unimagined just a few years ago. These hybrids, collaborations, and partnerships are having a significant impact on both formal and informal education.

The Difference between Informal and Formal Education

Informal education is education that takes place outside of a formal school setting, as opposed to formal education which is confined to classroom-based education with trained teachers. While formal education is set with a curriculum of set courses or content, informal education is not limited to classrooms. A person usually seeks out information that they want to learn about and can do so in any manner that they choose. This includes books, museums, libraries, zoos, informal meeting groups, magazines, and more recently E-learning media including the Internet, software, television, and video games (Greenfield, 2009). The web and E-learning tools easily and readily lend themselves as opportunities for informal education (Wolfe, 2001b). Users can access E-books, software and applications, informational websites such as Wikipedia, and video games at any time they choose so long as they have the proper tools (Greenfield, 2009). Learning tools built with common applications such as spreadsheets have been created for uses such as learning statistics, and are often available

online free of charge (Fisher and Wolfe, 2012). Computers, tablets, smartphones, E-readers, and video game consoles all allow users access to these resources. These resources lend themselves to development of spatial reasoning skills such as visualization, development of problem solving and critical thinking skills, and imagination (Greenfield, 2009).

Project Dragonfly

Project Dragonfly promotes inquiry-driven learning and educational reform, reaching people around the world through learning media, exhibits, and education programs. Project Dragonfly represents an evolving set of collaborations between a university and a variety of institutions worldwide including zoos, national parks, government ministries, nongovernmental organizations, and not-for-profit organizations. One dimension involves participatory media including the Dragonfly Web pages, perhaps the first website devoted to children and scientific inquiry (Wolfe et al., 2001). DragonflyTV, an inquiry-based public television program for children; and Wild Research Stations, interactive inquiry-based experiences at aquariums and zoos designed to increase engagement in science and conservation by involving families in research and conservation action. In addition, Project Dragonfly offers 'Earth Expeditions,' field courses around the world, online training for teachers, and Masters Degree Programs.

Through Project Dragonfly university students in traditional face-to-face classrooms have created web-based courseware for children, and students and teachers in hybrid or blended courses engage in online learning experiences culminating in collaborative face-to-face international field experiences in parks and preserves around the world. These collaborations blur the boundaries between informal and formal education, E-learning and fieldwork, and force traditional institutions to adapt to a rapidly changing landscape by embracing hybrid learning experiences, negotiating agreements among organizations, and acknowledging professional activities that challenge conventional notions of scholarship and teaching.

iCampus

The iCampus initiative was a partnership between Microsoft and the Massachusetts Institute of Technology (MIT) launched with the goal of improving technology-enabled teaching models and the development of new educational tools. The iCampus initiative set out to develop methods to allow users to remotely access laboratory instruments, create tools to exchange educational materials, provide access to distance learning and mentoring, and creates web-based virtual museums. Though the initial iCampus initiative concluded in 2006, there is now a project called the Outreach Initiative whose goal is to disseminate the educational technologies developed from the iCampus initiative. The iLabs project allows users to access online remote laboratories and conduct experiments that they might otherwise not be able to, given their limited resources. The Cross Media Annotation System (xMAS) enhances the use of video and images for courses that reference visual materials often. XTutor is a program that has audio recordings and transcripts of lectures, homework problems, and an intelligent tutoring agent online for introductory computer science and Artificial Intelligence classes. Another project is iMOAT, a web-based service that allows for grading of writing assignments and exams. Technology-Enabled Active Learning (TEAL) allows for an enriched learning experience by combining lectures, simulations, collaboration, and hands-on access to experiments from a student's desk. Finally, Peer Review Evaluation Process (PREP) is meant to be used by teams of four to six individuals so they can develop and share ideas with one another; for example, Mechanical Engineering students have used PREP to design and build robots for competitions. Tools such as these have the potential smudge, the line between teaching and research at large and small institutions around the world.

Online Learning Communities

Online learning communities are communities whose members connect via the Internet to engage in peer-to-peer learning. In these virtual-communities, a topic area will be defined and discussed amongst members to gain knowledge of the subject matter. Information can be shared through any Internet supported medium including: audio, video, text, pictures, Internet links, and virtual files. Community members can upload and download files as needed.

Social Networks

Social network sites such as Facebook, Twitter, and Google+ allow users to interact via the Internet with anybody across the globe. Facebook, the largest social networking site boasts over 1 billion registered users worldwide (Vance, 2012), and educators are turning to these sites to connect with their students. Teachers can 'post' relevant material to a social networking site and students can view the information and further explore the content (Davis, 2010).

This medium allows for a different and flexible learning experience for students. The use of social networking in education can be beneficial because students are continuously (and willingly) exposed to these networks, giving them easier, faster, and more convenient access to class material (Davis, 2010). Additionally, it allows students who would not otherwise participate in the classroom to engage in the content from the safety of their computer (Davis, 2010). Education-focused social networks, such as LiveMocha, provide instruction in foreign languages in a collaborative peer-to-peer learning environment. LiveMocha boasts over 15 million users, and feedback is 'crowd-sourced' such that users who want feedback must provide feedback to other members of the online community.

Podcasts

Podcasts are digital media files that are streamed online (Ovadia, 2007). Typically, podcast are delivered via an audio recording, but can also be delivered via video. Usually podcast are continuous series, covering a wide range of topic areas. New podcasts can be added periodically (Ovadia, 2007). By subscribing to a series, the user can automatically download the newest podcast file and can then listen to it via their computer or upload it to their portable media player or other device.

Podcasts can be easily utilized for educational purposes, such as lessons on physics, mathematics, psychology, history, or literature. Learners can download a podcast and listen to the lesson at their leisure. College professors have used podcasts as a way to provide students with an additional study aid to review a lecture or listen to one they may have missed (Ovadia, 2007).

Video Sharing Websites

Video sharing websites, such as YouTube, allow users to upload video clips to a website so that others may view it online. The content of these videos are wide ranging and sometimes sophomoric. However, individuals post and view a myriad of instructional and educational videos every day (Buzzetto-More, 2012). For example, there are 'how to' videos on how to tie a Windsor knot, how to cook turkey, and how to replace an ignition coil in a Buick LeSabre. TED talks are a popular series of brief lectures presented as video clips, with over 1400 talks on topics ranging from 'aid vs. trade' to 'the psychology of evil', all videos are available online. Educators can utilize video sharing websites to post lectures for students, provide supplemental content, or direct students toward another educator's videos (Buzzetto-More, 2012).

Blogs

Blogs, originally a combination of the words 'web log,' are informational websites that are usually written by one individual or small groups of individuals on a single topic. Visitors of blogs can sometimes leave messages, making the blogging experience more interactive (Luo and Gao, 2012). Most blogs provide text but other media such as images, videos, audio, and links to other websites can also be found. If a blog is used for educational or instructional purposes, it is sometimes referred to as an 'edublog.' A nonstudent user may use a blog to gain information about a subject. Whereas a student or educator may use a blog to provide instructions, ask questions, build on ideas, share tips and information, and as a forum for relevant discussions (Luo and Gao, 2012).

Internet Forums

Internet forums, or more commonly called message boards, are online discussion websites where individuals can have conversations by posting messages on a 'thread.' Similar to other online learning communities, a forum can range in the content it covers; threads generally target topics that are more specific. Postsecondary schools commonly use forums for individual classrooms, allowing students to have discussions, ask questions, and interact, with not only one another but their professor as well.

Wikis

A wiki is a website that is created and developed by multiple users working in a collaborative effort to add, change, or delete content. Wikis are web pages whose sole purpose is to provide relevant information to any given topic area. The largest Wiki is Wikipedia with 23 million articles in 285 languages, including over 4 million articles in English produced by anonymous volunteers from around the world. One study suggested no differences in, the rate of 'serious errors' between Wikipedia and a professionally produced encyclopedia (Giles, 2005) though this is still a matter of controversy. Recently, educators and their students have become involved in creating Wikipedia entries. For example, the Association for Psychological Science has involved more than 2000 psychological scientists and their students in the APS Wikipedia Initiative, "to represent scientific psychology as fully and as accurately as possible and thereby to promote the free teaching of psychology worldwide." The design of a wiki allows users to browse through a page and skip to other relevant topic areas through hyperlinks. Although Wikis are designed for collaboration, they do not easily lend themselves to social networking, but they provide an overview of relevant information (Buzzetto-More, 2012).

Mobile Learning Platforms

It has been suggested that mobile computing is the future of E-learning (Pierce, 2010; Schaffhauser, 2010). The creation of e-books, tablets, and the ubiquitous presence of smart phones are making mobile computing devices the platform of choice – especially for 'digital natives,' i.e., those of the generations who have never known a world without the Internet and an array of computer technologies (Halpern et al., 2012).

Mobile Computing

Mobile computing is the use of an easily transported computer such as a tablet that the user interacts with regularly throughout the day. This encompasses the use of mobile computing, hardware, and software. Mobile computers are capable of doing just about anything one can do from a desktop computer. Capabilities include Internet and email access, editing and accessing documents and images, playing games, and accessing applications and other programs. There are drawbacks to mobile computing that can make it somewhat harder to use when compared to a personal computer. Limitations include slower and less reliable Internet access, lower security, power consumption that exceeds the capacity of batteries, and smaller workspace. Some of the most popular methods of mobile computing are smart phones and tablets. Other mobile computing devices include portable computers, personal digital assistants (PDA), and graphing calculators.

Recently, educators have been encouraged to utilize smart phones in their primary school classrooms to engage students in learning. The benefits to using these technologies include an increase in student engagement, more accessibility, and larger student interest (Swan et al., 2005). Project K-Nect is one program that gives students access to smart phones and mobile applications that can explain algebraic principles and allows them to seek advice from their peers via text or instant messages; the program has shown improvements in student's academic success by 30% compared to their peers who did not use the program (Pierce, 2010). In addition, informal learning environments such as LiveMocha increasingly have versions of their entire suite of resources optimized for smart phone platforms.

Tablets and E-Books

Tablets are portable personal computers that come in many sizes and are usually operated with a touchscreen. Tablets come with an on-screen keyboard and the user uses their finger as a mouse, some tablets allow the user to connect these as external components. While today's tablets run on an operating system, initial attempts to make the tablet a portable replica of larger personal computers were not successful, and the trend has arguably been to make desktop computers more like tablets. Tablets utilize a touch user interface and mobile applications, called 'apps.' Many manufacturers, such as Samsung, HTC, Amazon, Microsoft, Google, and Apple, now produce tablets. Because of the commercial success of tablets, manufacturers can offer competitive pricing, making tablets affordable, widely available, and an acceptable alternative to a laptop or personal computer.

Because of the convenience and affordability of tablets, they are now being used in classrooms to replace textbooks and for general use by students (Schaffhauser, 2010). One benefit of using tablets in lieu of textbooks is having all books easily accessible and in one place. An additional benefit is the multifaceted uses tablets offer. Tablets allow students to become immersed in a learning environment. For example, students can quickly access the Internet, which provides vast amounts of digital content and converged media (Schaffhauser, 2010). Because tablets are essentially computers, they can be specialized with applications for children with learning disabilities. Schools in Africa have shown an improvement in learning outcomes over the course of one term when students were given tablets (The Economist, 2012).

An E-book, or electronic book, is a book in digital form that is usually read on an e-book reader or tablet, but can also be read on a computer or another electronic device that supports e-books. E-books can be bought online through a number of providers including: Amazon and the Apple eBookStore. Popular e-book readers include Amazon Kindle, Nook, Apple iPad, and Sony Reader. E-books can be stored on e-book readers or saved indefinitely in a server provided by the respective e-book store and accessed instantly when needed via an Internet connection.

E-readers and e-books provide many features that make owning them advantageous to having a physical copy of a book, especially in education. E-book websites can translate e-books into different languages if it has not already been done with a printed book (Harris, 2009). Additionally, some E-readers can read text aloud for those who are visually impaired, or otherwise prefer listening (Harris, 2009). E-readers also provide the ability to read the definition of a word by clicking on it, and allow for highlighting, bookmarking, and annotating texts and to see which passages other users have highlighted. Some E-readers allow readers to conduct searches for terms found in e-books, and look up more information about a topic using the same device (Harris, 2009).

Intelligent Tutoring Systems

One-on-one human tutoring has been found to produce dramatic gains in learning and Intelligent Tutoring Systems (ITS) employ Artificial Intelligence programming techniques with the goal of creating an ITS that behaves as a human tutor. Intelligent tutoring systems interact with people via dedicated computers or recently on the web. ITS can provide information, give examples, ask deep level reasoning questions (Craig et al., 2006), answer questions, explain answers, and give practice problems and demonstrations. Similar to human tutors, an ITS can make assessments about the knowledge a user has on the subject matter. This is useful because it allows the ITS to provide appropriate feedback and knowledge when it is most critical to the user. Furthermore, an ITS can scaffold learning, providing a good deal of support early in the learning process and remove support appropriately as learning progresses so that learners can build on their knowledge and skills in context (Bouyias and Demetriadis, 2012). Recently, there has been research on the automatic detection of learner emotions with an eye toward creating affect sensitive ITS (Graesser, 2011).

Intelligent tutoring systems have been developed for use in education, industry, and the military. Intelligent tutoring systems address a wide range of knowledge domains (Graesser et al., 2005b) including mathematics (Aleven et al., 2009), reading comprehensions (Mostow and Beck, 2007), argumentation (Bouyias and Demetriadis, 2012; Wolfe et al., 2009), physics (Gertner and VanLehn, 2000), health (Wolfe et al., 2013), legal reasoning (Pinkwart et al., 2006), and computer literacy (Graesser et al., 2003). Studies have found that some ITSs show improvements in learning amongst students compared to classroom only learning. Additionally, students have reported having better comprehension, being more engaged, having a more positive attitude, being more motivated, and having a positive effect on academic outcomes after working with an intelligent tutoring system (Graesser et al., 2003).

Some of the most effective ITSs are those that use mixed initiative natural language dialogues such as AutoTutor (Graesser et al., 2005a). Natural language dialogue means that dialogue is conducted in a human language such as German or English, and mixed initiative means that either the ITS or the learner may initiate a strand of conversation (D'Mello et al., 2010). In most ITS with natural language processing the learner types into a dialogue box (Wolfe et al., 2012). However, research is being conducted on completely oral dialogues (D'Mello et al., 2011). Intelligent tutoring systems that employ natural language dialogues include: CIRCSIM-Tutor, an ITS that helps students learn about blood pressure; Why2 Atlas, a physics ITS; and AutoTutor, an ITS that has been used to teach physics, computer literacy, and critical thinking skills (Graesser et al., 2005a).

Recently, ITS have expanded to web-based platforms, dramatically expanding the potential of ITS to have a broader impact on education. For example, in the city of Pittsburgh, Pennsylvania, USA, researches are bringing the ITS out of the lab and into the community, experimenting with the Andes Physics Tutor as an intelligent homework helper for physics student in local high schools (Katz et al., 2007). AutoTutor Lite is the first cross-platform web-based ITS that engages in two-way dialogues with people in natural language (Wolfe et al., 2012). Talking animated agents converse with learners using Latent Semantic Analysis to 'understand' what they are saying and respond appropriately.

Immersive Environments

Immersive environments allow the user to fully experience a real or artificial environment (Burns, 2011). Because immersive environments are highly engaging, a user can have a rich experience. Immersive learning environments build upon the idea that students can learn better by doing rather than seeing (Dickey, 2005). There are many types of immersive environments ranging from virtual environments to augmented reality.

Virtual Environments

Virtual Environments or Virtual Reality is the immersion of a user in an artificial computer-simulated environment that is designed to emulate the look and feel of being in a real environment. Importantly, virtual environments afford actions – which can form the basis of experiential learning (Dickey, 2005). Virtual environments are rendered on a computer screen, projected onto external surfaces, or experienced with a head mounted display, permitting the user to move about freely in a virtual environment (Waller et al., 2007). Ideally, users experience the feeling of 'presence' (Riva and Mantovani, 2012) in virtual environments. The US military has used virtual reality to train users how to fly planes and simulate how it would feel to jump from a plane. The creation of large-scale virtual environments permits users to engage in (and researchers to study) complex full motor behaviors such as fielding a batted baseball (Fink et al., 2009). Recent advances using the technique of redirected walking have enabled researchers to program virtual environments that are potentially unlimited in size (Hodgson et al., 2011). Thus, in theory, learners could explore ancient cities, other planets, or prehistoric landscapes on foot.

Augmented Reality

Augmented reality is the experience of actual environments that is supplemented by digital information in the form of images, sounds, and texts (Sumadio and Rambli, 2010). For example, the Star Walk app for smart phones and tablets allows users to identify over 20 000 objects in the night sky. Sky Walk takes advantage of the built in GPS and Internet connections to provide an interactive 360-degree touch control star map that displays constellations, stars, planets, satellites, and galaxies that are currently overhead. Engineering labs have used augmented reality to conduct lab practices remotely and in interaction with an actual lab (Borrero and Marquez, 2012). In short, augmented reality has the potential to provide learners with contextualized information in real time to enhance learning experiences in the field.

Learning Games

In recent years there has been an increased recognition of the potential for computer games to transform the way people learn (Halpern et al., 2012; Shaffer et al., 2005). Games can be highly motivating, yielding more 'time on task' (one of the biggest predictors of learning outcomes in the psychological literature). Moreover, commercial video games are driving many of the technological advances commercial computing. Games can let people inhabit new roles and new worlds and think and act in ways that would otherwise not be possible (Shaffer et al., 2005). Learning is essential to be a successful player of video games. As Brian Waniewski, managing director of Institute of Play notes, "Games create a need to know…You find things out as you progress toward your goal" (Greenemeier, 2012). Toward these ends, the creators of learning games must create meaningful contexts and constrain decisions-making tasks in ways that are productive and psychologically plausible (Wolfe, 2001c).

A recent example of a digital learning game is ARA (Acquiring Research Acumen), a computerized learning game that teaches scientific reasoning and critical thinking by having players interact with avatars and play games to identify research flaws, develop hypotheses, and assess the quality of research questions (Halpern et al., 2012). One strand of the work on games and learning involves 'serious games' (Millis et al., 2011; Westera et al., 2008). Serious games involve players in complex decision making, reasoning, and strategic problem solving in complex multiplayer environments that emulate real-world contexts (Westera et al., 2008).

Another tack has been to investigate learning in the context of popular video games to better understand the implications of emerging technologies and shifts in popular culture (Gee, 2007a) including skill development and processing speed (Dye et al., 2009). With digital video games, users have to solve problems by learning about a topic. There are many benefits to using video games as learning tools. First, video games help with the development of problem solving skills because users must complete tasks to accomplish a goal (Burns, 2011). Second, because of the technology involved in video games, they can keep track of information over long ranges of time, allowing a user to leave and come back to resume learning. Third, video games can provide the user with information they do not otherwise have, thus improving their knowledge and skill-base. Lastly, not only will video games provide users with information but they can also assess learning and provide feedback to users (Burns, 2011).

Another important avenue is the study of online communities of interest, for example players of games such as *World of Warcraft*, who spontaneously engage in collaborative learning and 'social knowledge construction' for purposes such as improving their playing abilities (Steinkuehler and Duncan, 2008). Some of the characteristics of these communities include meritocracy (valuing competency over credentials) open access, collaboration, competition, and flexibility (Squire et al., 2008). A third approach has been to create and study player communities organized around learning games such as Civilization III to promote the learning of academic topics such as world history (Squire et al., 2008). Indeed a case can be made that the study of learning games are shaping contemporary learning theory (Gee, 2007b; Squire et al., 2008) with a renewed interest in active engagement, response generation, individualization, spaced practice, reciprocal teaching, 'multiple retrieval cues' (Halpern et al., 2012) as well as situated learning and social context.

Summary and Future Trends

The topography of e-communication and e-learning is changing rapidly, and the rate of change is increasing dramatically. At the level of technology, mobile networked digital devices are becoming faster, more powerful, and more ubiquitous allowing e-learning to occur most anywhere. 'Big data' may provide new tools for tailoring learning experiences to individual and cultural differences in many contexts. Emerging discourse technologies are opening alternatives to the keyboard with voice, touchscreen, and gestures increasingly viable as modes of interactive learning. Progress in hardware continues to be faster than progress in software, and progress in both exceeds social and psychological theory. Institutions of learning at all levels are being shaken by these changes, yet the hyperbolae about the demise of brick and mortar schools and universities is largely unjustified. Counterevidence includes astoundingly high dropout rates in massive online open courses, and the observation that they are not supported by a viable business model. Although there are real sociocultural changes embodied in digital natives, genuine learning is still very hard work, which does not lend itself to quick technological fixes.

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser—Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

James D. Wright
Orlando, Florida
January 2015

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Abstract

This article will describe some of the characteristics of the most widely used econometric software, trace the evolution of this particular type of computer program, and explore the role of computer software in the development of applied econometrics. We begin with a general discussion of econometrics. The specific methodology defined by this field both dictates and is strongly influenced by the software that practitioners use – we return to that issue later in the article. The distinctive features of the current vintage of econometric software and the progression of developments that has produced it are discussed next. Econometricians' tools and methods have changed over time, gradually evolving from an early emphasis on single and multiple equation linear models to the contemporary use of a huge variety of nonlinear techniques in addition to the traditional linear regression models. Software has evolved correspondingly, becoming more complex and flexible in the process. The common characteristics of software in econometrics are considered next. A natural progression has produced a broad similarity in both the look and feel and the capabilities of econometrics programs. As indicated earlier, the final sections of the article explore some of the interrelationships between econometric software and popular methods in econometrics.

This article will describe some of the characteristics of the most widely used econometric software, trace the evolution of this particular type of computer program, and explore the role of computer software in the development of applied econometrics. In order to discuss econometric software it is necessary, first, to define econometrics. We begin the discussion in Section Econometrics with a brief introduction to econometrics. Section The Evolution of Econometric Software describes the distinctive features of the current vintage of econometric software and the progression of developments that has produced it. Section The Characteristics of Modern Software discusses some of the common characteristics of software in econometrics. Finally, Section The Role of Software in the Development of Econometrics will suggest some of the interrelationships between econometric software and popular methods in econometrics.

Econometrics

Econometrics is a collection of methods and tools used to fit equations (economic models) to data. It involves both theory and measurement, and an overarching view of the process by which data come to be observed. The analysis begins with a theoretical explanation of some phenomenon, or a hypothesis about how some variables to be observed are related to each other. Measurement begins with the recording of some aspect of economic activity. Model building is the process by which these economic measurements are organized within the framework of one or more mathematical equations suggested by the economic theory. The principle behind this analytical framework is that of a 'data generating process' (DGP). There is an underlying statistical regularity at work that leads to the analyst's observation of their measurements. It is the characteristics of this underlying regularity, usually formalized as a probability distribution over random events, which are the objects of the econometric study.

In a familiar application of theory to data, observers collect pairs of observations on prices (P) and quantities (Q) exchanged in a market, such as the market for tobacco or fine wine, under the umbrella of a theory of 'demand.' The theory is embodied in a 'demand equation,' $Q = f(P|\alpha,\beta)$, which states that quantities traded are influenced by prices, and the nature of that response can be described by the relationship $f(\ldots)$ and the 'parameters,' α and β. The equation is made operational by computing statistics that provide information about the covariation of prices and quantities transacted in the market. Thus, β might be an overall measure of how responsive quantities are to changes in prices, and the data are used to deduce information about the specific value of β.

In an econometric analysis, the information in a data set which may include thousands or millions of values is distilled to a few equations which are claimed to describe the DGP. The intricacy of modern econometric techniques makes essential elaborate software with capabilities that extend well beyond the ubiquitous spreadsheet programs such as Excel (4) and Lotus (10) (which would be the nearest cousins to the software considered here). (Numbers in brackets refer to the list of computer programs in the Appendix.) Econometric software is used most frequently for the manipulation of large amounts of measured data for the purpose of constructing the equations that are the model of the process which produced the data.

The Evolution of Econometric Software

The earliest software in econometrics was single purpose sets of Fortran language (Formula Translation) code. The researcher who needed a program for a particular purpose would typically write it, or borrow it from someone else. One can find some of these programs in the appendices in some of the classic pieces in the literature, such as Nerlove and Press's (1973) development of the multinomial logit model, the first edition of Draper and Smith's (1981) exposition of regression analysis, Zellner's (1971) early work on Bayesian estimation, and, more recently in Kalbfleisch and Prentice's (1980) work on survival modeling. A typical journal treatment is Krailo and Pike's

(1984) exposition of a logit model for panel data, which contains a Fortran program listing for a standalone estimation program. Until the late 1960s, the journal *Econometrica* occasionally would publish short articles documenting computer programs developed by the authors.

Program Libraries

The process of building applications from scratch was made easier by 'libraries' of interchangeable parts for software development. The precursor to a very large group of programs currently distributed as the 'BMDP Library' (2) was a group of individual routines developed at UCLA in the 1960s under the heading of the 'BMD' (BioMedical) programs. These special purpose routines included subroutines for linear regression, Spearman rank correlation coefficients, cross tabulations, and so on. The BMDs initially existed as boxes of 80 column punched cards of Fortran code in the drawers of statistics labs. They maintained a common structure that allowed authors to write their own data setup programs to 'plug into' the package. Another programmer's toolkit that was circulated widely in the 1970s was the 'IBM SSP' (Scientific Subroutine Package) which was part of the documentation for IBM mainframe computers. This book contained Fortran and C listings of programs for such functions as inverting or decomposing a matrix, and computing a variance ('C' does not stand for anything). It was simply an extension of 'B,' itself a derivative of 'BCPL' (the BC Programming Language) and a contemporary of APL (A Programming Language). All were languages originally written to work with the Unix operating system on DEC's original PDP-11 computers.

Most of the difficult computations being done by econometricians at this time involved complex matrix algebra, data manipulation, and random number generation. A library of well-written subroutines combined with the efforts of the analyst was quite sufficient for application development. This approach to programming has not vanished from the landscape. The *Numerical Recipes* books (C, Pascal, and Fortran) by Press et al. (1986), contain the modern counterpart to the expertly written library of subroutines contained in the SSP. The BMD libraries still exist as the commercial BMDP (2) routines, and the IMSL programs (6) and NAG (Numerical Analysis Group) (14) routines are still used by scientific programmers and in the development of major software packages. (IMSL, itself, grew largely out of a public domain library of matrix programs, EISPACK/-LINPACK.) These provided the backbone for many early matrix implementations. They have since evolved to the (still) public domain package LAPACK (www.scd.ucar.edu/softlib/LAPACK.HTML and, see also NetLib at ORNL).

Integrated Packages

Early econometrics programs were single purpose Fortran programs that users passed amongst themselves and which grew over time as they were extended. The concept of a multipurpose, integrated econometrics package emerged in mid-1960s in the form of three particular programs, TSP (Time Series Processor), the Troll system, and B34S (which began as BiMed34; see Stokes, 1997). TSP (23) and B34S (1) have remained active and are still under development. The early incarnations of these packages were primarily devoted to different forms of linear regression and correlation, but they have grown into vast assemblages of hundreds of thousands of lines of code (still mostly Fortran). Development of today's two largest commercial statistics and econometrics packages, SAS (17) and SPSS (20) also began at this time, though generally in social sciences other than economics and focused on techniques largely different from those of interest to econometricians. The demise of the distribution of custom written, single purpose software began in the 1970s with the emergence of TSP, SAS, SPSS, and so on.

Development Settings

With the exception of E-Views (3), which is a fairly recent arrival, and of the language platforms, MatLab (13), S-Plus (16), Gauss (5), Maple (11), and Mathematica (12), which are arguably successors to Fortran, most of the major packages in current use began development as part of a cottage industry in the 1960s and 1970s, usually by an individual or small team of innovators. This is a distinct difference from the contemporary, corporate route to major software development. The modern development centers, such as SAS, Inc. and SPSS, Inc. are creations of the 1980s and 1990s. Nonetheless, many of the programs listed in the Appendix to this survey continue to be developed by small numbers of statisticians and econometricians whose names would be recognized by practitioners (most likely in association with literature encountered as part of their graduate studies).

Programming Languages

Wither the primitive programming languages, Fortran and C? Fortran dominated the scientific computing landscape for nearly four decades until the early 1990s, and remains the language of choice for many scientific applications, e.g., in physics and astronomy. The practitioner interested in writing a Fortran or C program may use one of the development kits for the PC (Windows) setting, such as Lahey (7) and Watcom (24). Time-shared systems, such as Sun Microsystems, also provide Fortran and C compilers and program libraries as part of the operating platforms. These vendors have extended the lives of Fortran and C as numerical language platforms, but this style of programming is a dying art. For software developers, Fortran is giving way to C, for example, in the full conversions of RATS (Regression Analysis of Time Series) (15) and SAS (17) and in the mixed language construction of LIMDEP (8). Individuals doing custom numerical programming increasingly rely on Gauss and its counterparts, MatLab, etc.

Recent developer's programming language implementations have gravitated toward the studio format. The studio platform consists of integrated tools for merging code in one or more languages along with numerous libraries and ancillary tools. The Microsoft Software Developers Kit (SDK) is a popular example. This approach to programming has become essential for the development of major programs. One of the very useful innovations is the seamless creation of mixed language (e.g., Fortran and C++) platforms that allow developers to exploit the best features of both these languages. The end result is that C, its successor, C++, and Fortran, continue

to play a major role in the development of modern econometric software, but only in the laboratories of developers, rather than in the toolkits of practitioners.

The Internet

Finally, in what may be a surprise given the breathless surrounding hype, it appears that the Internet has had little or no impact on econometric software beyond facilitating the transfer of files, programs, and information. It is otherwise difficult to discern any ways in which the actual mechanics of econometric computing have been affected by the creation or expansion of the Internet.

The Characteristics of Modern Software

The software used by modern econometricians is essentially of two types. Most empirical research is done using one of the large, integrated packages that contain collections of programs for a variety of models. (See the 'Econometrics' list in the Appendix.) In these programs, complicated models are built with single, compact instructions. If a technique has gained acceptance in the applied literature, then it will appear as an 'option' in at least some of these packages. In contrast, when a technique or model proposed by an econometrician involves new methods or novel kinds of computations, then it is not likely to exist yet as a feature in an existing estimation platform. The computational tools that this analyst needs will typically be developed using one of the more primitive programming languages, such as Gauss (5), MatLab (13), S-Plus (16), or, at an even lower level, one of the native programming languages, Fortran or C++.

Packaged Expertise

The term canned routine has long been used for programs that embody the econometric expertise needed by users. Some have argued that the use of such software locks practitioners into a limiting set of models. While the argument may once have had some merit, the huge variety of techniques and the customizability provided by most large packages makes the criticism moot for current purposes. In addition, contemporary software is mature enough that developers have incorporated optimal algorithms that purists who mimic the textbook mathematical formulations might not use, or even be aware of. Least squares provides an excellent example. The analyst who writes his own program for linear least squares regression is likely to rely upon the textbook matrix formula, $b = (X'X)^{-1}X'y$. But, this is not the most accurate method of computing a least squares coefficient vector. Many large packages use much more accurate techniques, such as QR and singular value decompositions that avoid inversion and moments accumulation altogether. For the individual researcher to develop complicated low level tools such as this may well be excessively difficult.

User Written Programs

The distinction between these two types of software is somewhat blurry since the programming languages are often distributed with packages of routines that have been written by expert users. In addition, developers of code for Gauss (5) and MatLab (13) often distribute their programs on the Internet simply by posting them on their own web sites, perhaps, along with the research report of which the software development was a part. For example, all the major integrated econometrics packages contain an estimator for the logit model for binary choice, whereas the Gauss user must program their own. However, so many widely distributed Gauss libraries of routines contain users' versions of the logit program that for practical purposes, Gauss does contain a logit estimator. In the other direction, large integrated packages usually contain their own 'programming languages,' which allow the user to construct capabilities that are not already contained in the program. Thus, while a program such as SAS (17) may not contain a specific command for estimation of a certain kind of survival model, it does contain a programming language for matrix manipulation as well as a means for a user to access certain utilities such as a nonlinear optimization program. Thus, the SAS user can develop a new estimator within his familiar SAS platform. TSP (123), SAS (17), SPSS (20), Stata (21), Shazam (18), EViews (3), and LIMDEP (8) to name a few, are all large integrated packages that also contain extensive matrix and data manipulation languages and access to nonlinear optimization programs which allow users to extend the modeling capabilities of the package. Thus, software developers and their users have blurred the distinction between preprogrammed procedures and programming languages.

Application Studios

The modern applied econometrician will usually maintain a toolkit of software consisting of one or more large packages, and, for less frequent usage, a low level development kit such as Gauss or MatLab, or a Fortran compiler, such as Lahey (7). Developers, conscious of this and sensing an opportunity, have begun to gravitate to a developer's studio format for econometric software. As noted, all of the large packages provide low to medium level programming capability. Current trends, such as EViews, LIMDEP, RATS, SAS, Stata, and TSP have brought the programming features closer to the front end of these large, high level packages and Gauss with its large, expanding, and widely distributed library is approaching the same format from the opposite direction.

Common Features

Most general, integrated econometrics programs are quite similar. The model-building process dictates the design, and as in many settings, a standard has evolved naturally. The following functions will be found in all the integrated packages, and, over time, will be mimicked by the users of the language packages as they collect their own routines:

1. Data input and transformation;
2. Model estimation – the estimation of model parameters, usually of several types;
3. Statistical inference – testing hypotheses and forming probabilistic statements about quantities of interest;

4. Specification, testing, and iterative refinement of model specification;
5. Manipulation of model results for forecasting and simulation; and
6. Graphics and display of results.

Programs differ in some features and there is some amount of specialization, but most or all of the preceding will be found common to all. (Reviews are regularly published, e.g., in the *Journal of Applied Econometrics*.) The second function listed is one of the major dimensions on which programs differ. For example, EViews and RATS are particularly oriented toward analysis of time series data, SAS and Stata are especially complete in their presentation of techniques used in biomedical research, and LIMDEP is best known for its selection of models for discrete dependent variables. (Markets being what they are, there is substantial and growing overlap of these features.)

Interfaces

The means of communication between the user and the software is the interface. In order to describe this, it is necessary to make a distinction between mainframe and 'PC' (desktop style) operation. A second distinction between 'batch' and 'interactive' mode use is also necessary. The two distinctions are useful for describing the way certain computer programs work, although both modes do appear in both settings. Econometric software design began on large time shared mainframe systems. The design of such systems necessitated a batch mode form of interface. In this case, the user submits a set of instructions to a computer (operator, real, or virtual) and returns later to retrieve their desired results. Modern computing carried out on the desktop, in contrast, usually involves an individual operating their own system interactively in the fashion of a large calculator, submitting single instructions (perhaps in the form of mouse clicked selections from menus) and instantly receiving the results of their directive. Econometric analysis often requires a hybrid of these two modes. Many estimation problems require huge amounts of computation that may take hours or days to complete, or lengthy scripts of operations. As such, a batch mode of operation is often necessary, even on a desktop computing platform. Therefore, there is normally some means of giving the program a directive equivalent to 'carry out the following sequence of commands,' or 'fetch the set of commands contained in a certain file on disk and carry them out.'

There is a qualitative difference in the typical look and feel of a desktop computer compared to a time-shared mainframe. Modern desktop software is based on graphical user interfaces (GUIs). The amount of menuing varies from one program to another, but all modern econometrics programs are based on the GUI format. In contrast, there is relatively little GUI in the time-shared environment. The distinction is only superficial, however. The numerical functionality of most econometric software is easily replicated in both mainframe and microcomputer environments (e.g., all of the econometrics programs listed below except EViews). This is one of the strong distinctions between econometric software and, say, the programs used for graphics design or word processing. In the final analysis, the purpose of most econometric software is numerical analysis that can be done equally well in batch or interactive mode.

Estimation Procedures

To describe some of the remaining features, it is convenient to define some terms. Estimation is a process of culling from a data set a set of statistics that summarize the process by which the data were created. Estimation results range from single numbers, such as the parameter β in our earlier demand equation example, to one-to-one transformations of the original data, such as a periodogram, nonparametric hazard function, or kernel density estimator. Econometric software will contain 'estimation routines.' The term derives from the earliest days in which Fortran 'subroutines' were written for these purposes. The estimation routine consists of a body of code written to be invoked with a simple 'command' and provided with the specifics of a user's problem. The command itself or the broader context of use of the software must define the kind of model to be estimated. Commands might be of the form 'Using the data on Price and Quantity, fit a linear regression model.'

For example, one popular program, LIMDEP, uses the following, fairly typical style:

$$\text{Regression; Lhs} = \text{Quantity; Rhs} = \text{One, Price \$}$$

that states in words that the user wishes the program to compute the constant term (ONE) and slope in a linear regression of quantity on price, $Q = \alpha + \beta P + \varepsilon$. All integrated packages have counterparts to this kind of command, which is provided to the program by means of some kind of text processor. Some packages provide the same functionality by asking the user to select the estimation framework, then the variables in the equation from menus, instead. Many programs also allow users to choose either mode of entry. Each has its virtues – the former allows recording of steps and reuse of commands, whereas the latter is generally more convenient.

A programming language such as Gauss would not contain such a broadly defined procedure. Rather, the Gauss processor would allow the user to define, using matrix expressions, the algebraic steps involved in doing the computation, including how to compute the coefficients for the model and how to compute certain statistics that the integrated processor would produce automatically. The user would then use the language's built-in functions for displaying the results of their computations. Thus it would seem that a great deal more work is required of the Gauss user than the LIMDEP user. There is, but two issues motivate the former. First, as noted, many such sets of computations already exist, in elaborate routines that programmers have written and disseminated, so that these procedures can be used, often with a single command. Second, many estimation techniques do not exist (yet) in large integrated packages, so this is the only way to proceed. (Since this market is fast moving, it would be inappropriate to mention specific techniques. By the time this article appears in print, the information will be out of date.)

The remaining functions involve manipulation of model results. Some of these are handled automatically by the software while others must be assembled by the user. At this

juncture, the user of the integrated procedure is likely to use some of the programming features of the package, such as a matrix computation. For example, the literature often produces new statistics or ways to manipulate the results produced by familiar models such as the linear regression model. The SAS, Stata, or TSP user is likely to handle this situation by constructing a 'procedure' with 'adjustable parameters' that might appear as follows:

'Procedure: Regression;
Dependent variable is (Y), Independent variables are (x1, x2)
Compute residuals as variable (e).
Compute and report statistics using procedure …
End of Procedure'

Now, to invoke their procedure, the user might use a single directive such as:

'Use Regression Procedure (Quantity, One, Price).'

The generality of the procedure allows it to be used for different problems just by changing the 'call' statement. At this point, the only difference between Gauss and SAS is the detail that will have to be programmed in the first line of the procedure.

Accuracy

One might think that given the textbook formulas for the necessary computations, all programs would get the same right answer for any particular problem. But, in fact, this is far from correct. Even in the absence of programming errors, there are large differences in the algorithms and methods used in computer packages. For practical purposes, two approaches are used for validating econometric software: replication and benchmarking. The first of these is strictly pragmatic. For most techniques, there are no applications with known *correct* answers against which to benchmark a program. As such, it is assumed that if two or more of the major programs give the same answer for a problem, then they both have it right. If they differ, then the tricky issue arises as to which, if either is correct and, again, the issue would have to be resolved in ad hoc fashion. A contemporary study that pursues this line of inquiry is Silk (1996), whose review of estimators for simultaneous equations models presents some surprising differences (see also, McCullough and Vinod, 1999.) The same approach has been taken in a review of programs for the computation of GARCH models by McCullough and Renfro (1998).

True benchmarking is now available for many common calculations. The tradition in econometrics begins with Longley's (1967) true results to 10 significant digits for a specific problem in linear regression. The Longley standard was used for many years as the yardstick for linear regression programs; if a program could match the Longley benchmark to at least eight digits, then it could probably rise above suspicion for practical usage. Later analysis has showed that the Longley hurdle is not particularly high, and clearing it is not all that difficult, even for fairly mediocre software. The Statistical and Engineering Division of the National Institute of Standards and Technology (NIST) has published (www.nist.gov/itl/div898/strd) a suite of 57 benchmark problems in four classes: univariate statistics, analysis of variance, linear regression, and nonlinear regression. The NIST problems have been solved using very high precision methods, and correct answers have been published. In detailed reviews, McCullough (1998, 1999) found fairly wide differences in the performance of several econometrics packages. Since econometrics programs tend to be revised, refined, and updated very frequently, these differences are likely no longer to be evident by the time this article is in print.

The Role of Software in the Development of Econometrics

A convincing case can be made that several parts of modern econometrics awaited the development of software to gain currency.

In primitive incarnations, econometric software operated on a table of data with variables in columns numbered from left to right. To communicate a desired computation to a program, the user would specify columns of the table, as in 'Regress the variable in column 5 on a constant, and the variables in columns 6, 8, and 10.' TSP was among the first to allow names for variables to appear in a symbolic instruction to the program. The software went an important step further in that it allowed the components of equations to appear symbolically in words and familiar algebraic symbols. Software had begun to evolve in this direction, but TSP brought the language of equation specification up to the level of compilers, such as Fortran. This major innovation changed the standard for econometric estimation programs.

The most important single development in practical econometrics in the period prior to 1970 was arguably the LSQ (Least Squares) procedure in TSP. The combination of symbolic equation specification with TSPs LSQ procedure allowed the birth of a very large literature on linear and nonlinear equation systems. The seemingly unrelated regressions model had been proposed a decade prior by Zellner and Theil (1962) (with Zellner, 1962), but the model did not appear in wide use until the appearance of LSQ. The procedure went an important step further in that it allowed the Zellner estimator to be extended to nonlinear systems of equations.

At roughly same time, Joreskog proposed a maximum likelihood approach to factor analysis and the estimation of general linear equation systems. The analytic results had been known for some time, but solvers for the likelihood equations for a general hierarchical linear equation system had not been widely distributed. Joreskog's (1970) early work included 'A Computer Program for Minimizing a Function of Several Variables,' (Educational Testing Services: Research Bulletin 70-14). In this was published the numerical engine of a package published 2 years later as 'LISREL' (Linear Structural Relationships – originally, ACOVS for Analysis of Covariance Structures). ETS 70-14 contained a listing of Fortran computer code for optimization, including a very clever and effective technique for the line search step in optimization. LISREL spawned a very large and still growing industry in structural equations analysis in the social sciences. The technique is a major part of the methodology; the program, itself, has become Scientific Software, Inc. (9).

Of somewhat more recent vintage, is Heckman's (1979) sample selection model. Building on his work on labor supply models, Heckman proposed a method for a regression model with a particular type of nonrandom sampling in a seminal paper in 1979. The computations involved are now fairly routine and incorporated in most econometrics packages, but in the mid-1980s, the technique became a standard tool in the microeconometricians kit as the LIMDEP program (8) became the *de facto* standard approach for implementing it.

The work of Sims (1977), Granger (1969), and Litterman (1986) in the mid-1970s on vector autoregressions (VARs) in econometric time series analysis produced a new body of theory to challenge the structural simultaneous equations models. The RATS (15) computer program, developed by these authors carried the methodology into the mainstream of applied econometrics. The development has also been ongoing, both of the program (Estima, Evanston, IL) and of the methodology as can be seen in any reference on time series, such as Hamilton (1994). (RATS has recently spawned CATS – Cointegration Analysis of Time Series.) Once again, the computations and the methods are not overly difficult, but the fact that they have been conveniently integrated into a general-purpose package has been an important impetus to the dissemination of the methodology in the applied literature. RATS was also an early contributor among several that significantly advanced practice by providing the user with access to an optimization program that required only a basic, again symbolic, specification of the problem. This freed the researcher from having to learn a large amount of programming. Contemporary programs, e.g., TSP, LIMDEP, and SAS, still RATS, Gauss, and so on, all offer this capability.

The earliest work in applied econometrics required the analyst either to use someone else's program or to know how to write their own Fortran code. The latter type were in a distinct minority, so most researchers used software written by others. Current practice and contemporary software make it possible for researchers to choose among a vast array of pre-packaged techniques and, with the aforementioned MAXIMIZE capabilities and the matrix programming languages of Gauss, B34S, LIMDEP, RATS, and so on, to create another vast array of extensions with easily acquired programming skills. The result has been an explosion in the variety of techniques and model formulations found in the published research.

Conclusion

The development of software has been a facilitator, and a platform for the dissemination of results and continued research in econometric techniques and methodology. But there are cross-currents in contemporary software design. As of 1999, econometric software design and publication has left the cottage industry of the 1960s and 1970s far behind; it is usually (though not always) a corporate endeavor. At the same time, technique, development, and extension of econometric methodology remain the bailiwick of a scientific community which has, to some extent, preserved the distinction between the purely commercial nature of, for example, the word processor market and the romantic, if antiquated, free exchange of scientific software among individuals and small teams of researchers. However, market competition appears to be working smoothly in the right direction, and no case could reasonably be made that market forces have inhibited the development of econometric techniques or software in the way they have, e.g., in the markets for operating systems and Internet browsers. Technological advance in software and econometric technique appears to be rapid and uninhibited.

The above is a representative list of the most widely used econometric software. For additional information about the individual programs, the reader may refer to the web sites listed. Some of these programs are listed as econometrics although econometrics is not the major functionality of the program neither is its largest user base econometricians. These would include, for example, SPSS and Stata.

Abstract

The statistical side of economics began to emerge in the late nineteenth century, but it was only in the 1930s and 1940s that its conceptual and technical foundations were established under the label of econometrics. From the 1950s onward, as the discipline matured, a variety of approaches flowered, prompting debates not just about technical issues, but about foundational issues of modeling and statistical approaches.

Econometrics, the statistical metric for economics, can be regarded as one of the main innovations that turned twentieth century economics into an engineering, or tool-based science, in which each application of economic theory requires special shaping to circumstances, whether for scientific purposes or in the policy domain (see Morgan, 2001). The development and use of statistical tools for economics emerged in the early part of the twentieth century and, by midcentury, problems had been defined, solutions approached, and usable concepts developed, so that one could legitimately refer to a distinct body of knowledge embracing both theory and practice. After 1950, econometrics became a mature field and the dominant method of applied economics.

The particularities of the history of econometrics have often been linked to the nature of its tasks and aims (see De Marchi and Gilbert, 1989; Morgan, 1990; Qin, 1993; Boumans, 2005; Gilbert and Qin, 2006; Le Gall, 2007; Louçã, 2007; Boumans et al., 2011; Qin, 2013). Economists have understood their fundamental methodological problem to be: how to establish knowledge about economic phenomena and economic laws, given that most economic activities cannot be subjected to controlled experiments. Econometricians have assumed that, this means that descriptions, regularities, and relations of the economy must be extracted from 'passive' observations: statistical data that result from the natural course of economic activities, with the use of statistical theories and tools. Econometrics therefore suffers from all the usual problems of an inductive science. When measurement or testing of theories is at stake, severe correspondence problems arise because of the huge gaps between the assumptions of those economic theories and the conditions of data collection.

The history of the field also has its external dynamics (Desrosières, 1998; Epstein, 1987). To begin with, technological changes play an important role, evidenced in the development of the field of mathematical statistics and machines of computation (Renfro, 2011). The provision of data, the availability of trained econometricians, and fashions in economic theory are all relevant to the narrative, as are the stimuli from twentieth-century economic events and associated demands for econometric expertise. Econometrics in the latter twentieth century became a mainstay of economic policy analysis and tool for economic intervention, yet at the same time it grew into one of the most technically demanding and methodologically sophisticated areas of economics.

The Development Era

In the latter nineteenth century, a few economists began to use graphs and tables of statistical data to provide empirical support for their arguments, or to describe behavioral characteristics of economic phenomena (Klein, 1997; Maas and Morgan, 2002). They were quick to take up certain statistical techniques developed for biometrics, namely correlation and regression (Aldrich, 2010). But these 'measures of association' were not entirely adequate for economists' questions (Aldrich, 1995; Morgan, 1997). Where biometricians had, for example, a sample of heights of fathers and their sons, whose relation could be assessed with correlation or regression coefficients under reasonable assumptions about the individuals in the sample, economists typically used time-series observations that provided only one datum for each time date. Not only were such 'samples' considered peculiar from the viewpoint of the correlation theory of that time – which assumed that the observations within the sample had been independently drawn – but economists also believed that such time-series observations reflected a number of concurrent behavioral characteristics or causal relationships varying with the time element and unit chosen.

This problem of extracting causal relationships between variables from data that contained different time patterns dominated early econometric work, but the questions attacked were driven by economic and policy concerns. Measurements, for example, of market demand and supply relations for agricultural goods were undertaken at the American Bureau of Agricultural Economics during the 1920s when farmers faced falling prices in international markets and followed earlier European breakthroughs on these questions. Similarly, the problems posed by 'business cycles' were widely recognized by commerce, politicians, and economists, for the crash of 1920–21 was only outdone by the even more spectacular and longer-lived depression of 1929–33. Business cycle research institutes, which had begun to emerge even before the end of World War I, sprang up everywhere in the 1920s from Massachusetts to Moscow, but their truly international quest for description and explanation of the business cycle showed that the task of establishing measures of – let alone explanations for – that phenomenon, its characteristics, and its time patterns was incredibly difficult (Armatte, 1992).

 http://dx.doi.org/10.1016/B978-0-08-097086-8.71077-4

A concerted movement to create a more 'scientific' economics, based on both statistical and mathematical tools in economics, resulted in the foundation of The Econometric Society (in 1932), and its house journal *Econometrica* (in 1933) (Bjerkholt and Dupont-Kieffer, 2010; Louçã and Terlica, 2011; Bjerkholt and Qin, 2011). The most critical innovation of that decade, often overlooked, was that of the 'econometric model' formulated as an intermediary device to bridge the gap between economic theory and economic data. Such models represented elements of the economic theory in mathematical form, but were also attuned to the peculiarities of the time patterns of data evidence. With the use of such models, various kinds of knotty correspondence problems at the intersection between economic theory and data begun to be understood and solutions proposed. For example, the possibility of determining the individual effects of the contemporaneous variables in a system of simultaneous equations (the identification problem) was separated from the general problem of disentangling statistical relations where economic variables proved interdependent in multiple ways (the confluence problem), and where measurement errors were critical to the outcomes. But these 1930s answers were proposed as one-off solutions to specific applied problems, not general solutions for generally recognized problems.

However, econometrics was not without its detractors and the move to codify and formalize these somewhat-disparate concepts, problems, and emergent solutions seems to have been triggered by the Keynes–Tinbergen debate in the late 1930s. Jan Tinbergen, a young Dutch economist, was the most creative of the econometricians of the 1930s in the development of modeling, understanding conceptual problems, and suggesting solutions. He was also responsible for building and using the first macroeconometric model to analyze policy options. In this work, he developed ideas by Ragnar Frisch, a Norwegian econometrician (which later made them joint winners of the first Nobel Prize in economics in 1969) who in turn had drawn on the statistical work by English statistician Yule and Russian econometrician Slutsky.

Tinbergen's macroeconometric modeling work was heavily attacked by Keynes, and this attack, along with a number of other developments, prompted a search in the 1940s for more rigorous foundations for econometrics. Despite their difference of opinion, both Tinbergen and Keynes can be seen, in retrospect, as reshaping economic theory and policy in the aftermath of the Great Depression so that, in the 1950s, Lawrence Klein (Nobel prize 1980) could develop the postwar generation of macroeconometric models on Keynesian theories with more secure statistical foundations.

The key development in this foundation work was the 'probability approach,' fashioned in the early 1940s by Trygve Haavelmo (Nobel Laureate in 1989 for this work) (Bjerkholt, 2005, 2007; Bjerkholt and Dupont-Kieffer, 2011), a Norwegian econometrician, who proposed to use probability theory to establish a bridge between economic theory and passive economic observations (Boumans, 2010, 2014). His bridge was designed to carry the burden in both directions: to provide guidance on how to specify econometric models as statistical hypotheses so that not only could economic theory be logically related to economic data but that there would also be a path for inference back from the data to the theory.

Establishing the Mature Discipline

Haavelmo's probability blueprint for econometrics had indicated directions for both theoretical and applied work and has been interpreted as creating a 'revolution' in econometrics. Parts of Haavelmo's program were immediately elaborated at the Cowles Commission (later Cowles Foundation), an American hothouse of econometric research in mid 1940s (see Hildreth, 1986). Their research was primarily concerned with developing appropriate identification conditions and estimation (measurement) techniques for a system of simultaneous equations, assumed as a general representation of econometric models. In the years after 1950, an established orthodoxy developed based on the Cowles Commission's work and enshrined in textbooks in the 1960s. But, despite an active program of research at the theory level, providing technical extensions to this groundwork, cracks in the orthodoxy began to appear.

Applied econometric research revealed serious practical and methodological limitations in the Cowles approach, particularly in regard to model specification, model choice, and associated testing procedures. Their assumption that econometric work is anchored on a priori theories meant that it was rarely possible to falsify those theories empirically. The validity of the assumption was questioned in various contexts in the 1950s. For example, the Swedish econometrician Herman Wold, who was trained in the Russian probability school and time-series analysis in the 1930s, attacked the Cowles focus on simultaneity and developed alternative dynamic interdependent equation models in the 1950s (Morgan, 1991). But systematic contentions did not arise until after 1970. One of the first alternative approaches to challenge the Cowles approach was the specification search and sensitivity analysis using Bayesian methods developed by Ed Leamer (Qin, 1996, 2013). Other alternative approaches targeted the lack of attention to the characteristics of time-series data in the Cowles methodology. One such was the Vector Autoregressions (VARs) modeling approach pioneered by the American economist Thomas Sargent and econometrician Christopher Sims during the 'rational expectation' movement in macroeconomics (Qin, 2011). The VAR models effectively generalized Wold's dynamic models and turned a priori theories into possibly testable hypotheses embedded in VARs. But the methodologically most comprehensive approach was the dynamic specification approach initially developed at the London School of Economics (LSE) and led mainly by David Hendry (Qin, 2013). The LSE approach inherited the time-series research tradition from the Department of Applied Economics at Cambridge in the 1940s and 1950s under Richard Stone (Nobel Laureate in 1984), and synthesized various elements from the Bayesian approach and the VAR approach. It not only turned a priori theories into testable hypotheses, but also formulated them into a model type called an 'error correction model,' analogous in form to servo-mechanistic control engineering, and which could be more readily understood in terms of individuals' reactions to changing economic events. The error correction model subsequently became associated with the 'cointegration' theory developed mainly by Clive Granger (Nobel Laureate in 2003) to capture the long-run tendency of stochastic

cotrending among economic variables as an equilibrating force. These developments have effectively reversed the Cowles approach and made model choice and design depend explicitly on both a priori theories and data features.

On the other hand, the Cowles tradition was strengthened by the emergence of an especial microeconometrics that occurred concurrently with these changes in macroeconometrics. In the early 1950s, Stone had struggled with the immense task of providing measurement structures appropriate for the separate components of demand in a total consumer expenditure system: a system simultaneous at the microlevel. By the 1970s, various statistical models appropriate for explaining behavior at the individual level had been adapted from 1930s biometrics into econometrics by Dan McFadden and James Heckman (joint Nobel Prize in 2000). Their treatment of survey data enabled measurement models to be developed for the discrete choices made by individuals. Such discrete choices dominate economic decision making in consumption decisions, work decisions, family formation decisions, and so on. These measurement models were quickly taken up for they matched the individual utility-maximizing framework of neoclassical economic theorizing, the main orthodoxy of post-1950s western economics. Since the focal task of microeconometrics was to measure specific effects dictated by a priori theories, which amounted to utilizing the survey data information in a very partial way, the Cowles approach was found to fit well with the purpose (Heckman, 2000, 2005).

However, the growth of economic data has encouraged various data-instigated research to go beyond any straightjacket methodology. In financial econometrics, for example, the research for developing various composite indicators, reminiscent of the 1930s business cycle work, has become increasingly popular. In empirical economics, the rapid expansion of computable general equilibrium analyses, developed by Finn Kydland and Edward Prescott (joint Nobel Prize in 2004) in the early 1980s, has resulted from a hybrid of the Cowles approach with computer simulation methods. Such 'microsimulation' methods were pioneered by Guy Orcutt in the later 1950s to analyze demographic and social structural changes in association with time-series statistical analyses (see Morgan, 2012: Chapter 8). In computable general equilibrium models, parameters are 'calibrated' rather than statistically 'estimated,' although the calibration process takes into consideration the existing econometric evidence concerning the plausible parameter magnitudes and also the time-series properties of the modeled variables. Finally, explicit notions of experimental design are now found in the way econometrics is used to measure experimental effects in 'natural experiments': this has regenerated the founding fathers' earlier understanding of econometrics as a statistical substitute for experiment on Nature's passive data.

The Place of Econometrics in Economics

During the early years of The Econometric Society, 'econometrics' had been defined as the union of economics, mathematics, and statistics. And, in developing model intermediaries based on mathematical economic theory in that period, econometricians had developed a distinctive path compared to those found in psychometrics and sociometrics in the same period. After 1950, as economic theorizing became generally expressed in mathematical terms, the term econometrics stabilized on its current meaning: the use of statistical reasoning and methods as means to establish data-based descriptions of economic phenomena and empirically based counterparts for, and tests of, economic theories.

The spread of econometrics as an established part of economics in the post-1950s period may be understood as due not only to the strengthening of its foundations in statistical theory but also to the continuing expansion of data ('official' statistics), its establishment in the core undergraduate teaching program, and the development of cheap desktop computing. Together these meant that econometric work became a standard tool of policy work in governments and international agencies as well as becoming endemic, in various different forms, in the subfields of scientific economic research. Econometric theory has developed into a formidable body of specialist statistical theory and the increasing gap between the difficult technical and theoretical questions and the apparent ease of applications might indicate a field where applications came loose from theoretical work. This has been militated by another tool, the development of specific software packages for econometrics, in which theoretical and technical developments can be quickly translated into modeling, measurement, and testing regimes at the level of applications.

This widening use of econometrics did not denote a settled field. The community in the latter part of the twentieth century found itself immersed in a number of vibrant and important arguments about how to do econometrics, based upon applied econometric experience as much as on considerations of statistical theory and philosophy of science (Hoover, 2006; Spanos, 2006). Should models be theoretically based or descriptively accurate? What are the relevant criteria, economic and statistical, which can be used to test the adequacy of these different models? Should the modeling process start with simple models that grow more complex, or start general and aim to become simple? Should the probability framework be classical or Bayesian? What implications does this difference have for the types of measurements made and the possibilities of inference? How far can applied econometrics be formalized and codified apart from tacit knowledge? The terms of the continued debates around such themes point to a mature field, one intimately connected to both statistical and economic theory, but in which the foundational arguments raised in early work continue to reverberate to the most recent time.

Abstract

Anthropologists study economic practices as integrated features of specific societies, comparatively, and as a set of historical, often diffusionary, patterns of thought, power, and organization for production, distribution, exchange, and consumption. Their foundational concerns have shifted from the description and interpretation of reciprocity and redistribution and the technological and social capacities for sustaining livelihood in small-scale and nonmarket societies to the analysis of the wide variety of articulations with and transitions of nonindustrial societies to participation in worldwide economic formations. Increasingly, economic anthropologists are studying phenomena of direct concern to other economists and social scientists, such as the internal activities of transnational corporations, global financial markets, and the sustainability of contemporary economic systems.

Introduction

Economic anthropology is concerned with how human societies sustain themselves materially and socially through schemes of production, distribution, exchange, and consumption.

In keeping with the orientation of the discipline of anthropology as a whole, economic anthropologists have sought to understand economic practices (1) in relation to the specific societal context in which they occur, (2) comparatively, in relation to similar activities as they have been observed in other times and places, and (3) as a set of historical, often diffusionary, patterns of thought and organization. The first is intended to contribute to the understanding of given societies, in which economic processes are understood to be an integrated subset, while the second leads to the broadening and refinement of common economic concepts for the benefit of theoretical frameworks. The third has been predominated by the study of capitalism, colonialism, and development, as these have been the prevailing forces for economic change since the subdiscipline's start.

A Heterodox Alternative to Neoclassical Economics

From its inception, economic anthropology has implicitly or explicitly drawn many of its basic questions in relation to the more influential field of economics. While economics is a varied, dynamic discipline, one can nevertheless begin to trace the intellectual history of economic anthropology by citing the central premises of neoclassical economics and then showing how anthropologists have sought to differentiate their approach in opposition to or in supportive modification of these premises.

The Neoclassical Economic Approach: Maximization, Market Equilibrium, Stable Preferences

Gary Becker, professor of economics and business at the University of Chicago and winner of the 1992 Nobel Prize, says: "The combined assumptions of maximizing behavior, market equilibrium, and stable preferences, used relentlessly and unflinchingly, form the heart of the economic approach as I see it" (Becker, 1976: 5).

Anthropologists observe that these three assumptions comprise an implicit theory of social morphology and human nature with claims to ahistorical universality.

First, *maximization* means that people predictably "choose the alternative that gives the most satisfaction, value, or benefit in a context of limited means ('scarce resources')" (Plattner, 1989: 7). The notion that people everywhere maximize or 'economize' in this way suggests both the universally perceived experience of resource scarcity relative to needs and wants and a view of human beings as predominantly rational, choice-making creatures.

The emphasis on *market equilibrium* points, first, to the tendency in current economic thought for the economy and the market to serve as interchangeable concepts. The notion of equilibrium suggests that the market is self-correcting toward balance and efficiency (through laws of supply and demand, for instance) and providential in its propensity – when not meddled with – to contribute to the wealth of nations. Markets, in turn, can behave in this way only if all goods and services (including land, labor, and capital) are available to be traded and are convertible, especially through the medium of money.

Transactions in the market, finally, are based upon *stable preferences*, which are defined as being 'revealed' in the market through the choices consumers make. Market choices and transactions are held to add up to familiar concrete and abstract economic institutions, such as the used car or labor markets, rather than the reverse. They are also analyzed by some economists as determinative of behavior in many institutions not ordinarily thought of in economic terms, such as the family, ethics, communal solidarity, or art.

Within markets, thus broadly defined, individuals are seen to pursue their preferences in rational, maximizing, competitive, and ultimately self-interested ways, independent of or even in opposition to communal norms and expectations. The unit of analysis is the individual decision-maker rather than the group, which may itself be seen as an epiphenomenon of economic transactions. Geographical or sociocultural

environment, historical precedent, and various other intermediary institutions are factored out.

The Anthropological Position

There is an inherent discord between the kind of research inspired by these assumptions and that which is carried out by anthropologists. In result of the naturalistic, descriptive methodology of the discipline, anthropologists tend to find universal laws unhelpful.

Anthropologists have described a variable spectrum of economic systems. In doing so, they have found it necessary to modify the conventional economic lexicon (property, value, money, investment, etc.). Often, even a modified version of the economist's vocabulary is found wanting in its ability to capture local practices, and native terms must be used instead. *Kula, moka, taonga, hxaro, dana, giri, guanxi*, etc., refer to non-Western economic concepts, practices, and systems that have no equivalent in the West and are therefore unexplainable using the lexicon of conventional economics. Comparative analysis involving these culture-specific terms has yielded general insights that unfold by way of compelling analogies rather than obeisance to a purportedly universal set of laws.

Extrapolating collective phenomena from aggregates of individual behaviors is perhaps the greatest difference separating the two disciplines. Anthropologists do not conceive of human thought or action as dissociable from culture, and they take it as their charter to decipher local social logics of action. Even the sizable contingent of economic anthropologists who are model oriented, and/or who specifically study individual decision-making, resource allocation in competitive conditions, risk behavior, and similar mainstream microeconomic subjects – even those who find that their research supports formalistic assumptions of rationality and utility maximization – nevertheless, as Michael Chibnik says, take into account "the historical changes, cultural norms, and socioeconomic institutions that constrain the choices possible for different groups of people at particular places and times" (2011: 1).

In consequence, it makes sense to view economic anthropology's rich empirical and theoretical explorations simultaneously in terms of their contribution to disciplinary anthropological concerns and as part of a debate with economics and other policy and social science disciplines that have adopted neoclassical economic methods and assumptions.

Foundations and Orientations of the Subdiscipline

Gifts, Commodities, and the Nature of Exchange

The person generally credited with awakening scholarly interest in primitive economies was Bronislaw Malinowski (1884–1942). Malinowski described the kula system in the Trobriand Islands of Melanesia: "a form of exchange, of extensive, inter-tribal character … carried on by communities inhabiting a wide ring of islands, which form a closed circuit" (1922: 81). Two kinds of articles are exchanged in the kula: red shell necklaces, which move in a clockwise direction around the network of islands, and white armshells or bracelets, which circulate in the opposite direction. "Every movement of the Kula articles, every detail of the transactions is fixed and regulated by a set of traditional rules and conventions, and some acts of the Kula are accompanied by an elaborate magical ritual and public ceremonies" (1922: 81).

Malinowski believed he had discovered a counterexample to conventional economic views of his day: That an elaborate system of long-distance trade could not be organized without markets, money, or states; that the purpose of material exchange, perhaps especially in premodern societies, would be oriented only to utilitarian purposes; and that grasping, rational self-interest above all else would dominate systems of exchange everywhere.

The kula has been restudied and reevaluated, in keeping with current analyses of exchange. It also continues to be used as a staple in undergraduate education, at which level the key lesson may be that in the Trobriands and in many places where anthropologists have studied, the purpose, process, and effects of material exchange is, alongside or independent of whatever utilitarian purpose it may carry, inherently *social*. As Strathern and Stewart say of the kula, "The giving of an item, or a series of items, was explicitly designed to obligate a partner to make an appropriate return later. Thus, gifts bound people together, and in doing so helped to create the fabric of society on an interpersonal basis" (2012: 230).

This 'gift' aspect of the kula fascinated a contemporary to Malinowski, the French sociologist Marcel Mauss (1872–1950), who cited the kula, among other examples, to make several arguments that dominated exchange theory in anthropology for several decades. Mauss' 1925 essay, *The Gift: Forms and Functions of Exchange in Archaic Societies*, contained or implied the following claims:

1. The impersonal and individualized form of commodity exchange dominant in modern societies is not primordial or universal.
2. Systems of credit and contractual obligations are ancient and, in variant forms, widely found.
3. Prestations, as Mauss referred to gift exchange in early societies, were characterized above all by their composite or 'totalizing' nature, in two respects. First, the phenomena are not discrete: each "contains all the threads of which the social fabric is composed … religious, legal, moral, and economic" (Mauss, 1967: 2). Second, in such societies one often finds entire groups and not just individuals participating in exchange events. Thus, the logic of gift exchange was not to be sought in the economic sphere per se, but in the realms of kinship, politics, and collective ritual.

As an important addendum, while Mauss used the term gift (*le don*) to characterize exchange systems dominant in early societies, this does not mean that exchange was always friendly or given with generous intentions, as our understanding of the word gift might imply. Gift exchange could often be agonistic and competitive. Mauss generalized from the example of the potlatch, practiced among American Northwest Coast Indians. Potlatch was a ritualized exchange where competing chiefs made public displays of exaggerated generosity, the aim of which was "to crush a rival chief with excessive obligations that cannot be repaid" (Yan, 2012: 280).

Finally, Mauss' essay initiated a long continuing inquiry into the nature of person–object relations. The opening

question of *The Gift* is, "What force is there in the thing given which compels the recipient to make a return?" (1967: 1). Mauss drew on the Maori concept of *hau*, a mystical force purportedly located in exchanged valuables that draw them back to their places of origin, not literally, but through the medium of a countergift. How people relate to objects, and through objects to each other, is key to Mauss' thought because it is not just the style of exchange that may differ typologically between market and nonmarket societies, but also whether or not the objects themselves are transferrable ('alienable') or not ('inalienable'), and what makes them so.

Despite, and in some ways because of, its terseness, *The Gift* has inspired more debate than any other text in the history of economic anthropology. In the 1960s and 1970s, when anthropologists joined in political economic critiques of globalizing capitalism, some found it useful to draw upon Mauss' work to oppose gift to commodity-oriented societies, and reciprocity to market exchange. In the 1980s and 1990s, edited volumes such as *The Social Life of Things* (Appadurai, 1986), *Money and the Morality of Exchange* (Parry and Bloch, 1989), and *Barter, Exchange, and Value* (Humphrey and Hugh-Jones, 1992), as well as many articles and monographs (e.g., Carrier, 1991; Gregory, 1982; Weiner, 1992), meticulously disentangled the issues surrounding the gift/commodity dichotomy. A survey of research being published today attests to the ongoing fruitfulness of the gift/commodity complex as a way of evaluating systems of exchange as well as individual rationales in both non-Western and Western contexts.

The Economic Constitution of Society, or the Social Constitution of the Economy? Reciprocity, Redistribution, and the Market

It is possible to read into Mauss's work the notion that in early society exchange functioned as a kind of social glue that held societies together. This functionalist notion has fallen from favor, but not anthropologists' tendency to view human beings as above all social rather than economic utility maximizing animals. In which case, the view of economic rationality as the prime determinant of individual behavior, and the market or market-like exchange as the foundation of social organization, might seem unnatural, even absurd.

How the 'economic man' view came to predominate, and the consequences of it, was the focal point of the work of a Hungarian economic historian, Karl Polanyi (1886–1964), whose ideas have had a lasting impact on economic anthropology.

Like Mauss, Polanyi looked to historical and ethnographic data to base a contrast between principles of a natural economy and those of market fundamentalism (epitomized in the belief in the 'self-regulating market'). Polanyi thought of the self-regulating market as a utopian idea that had raged out of control to become one of the great dehumanizing forces in history. Hann and Hart write: "Following Aristotle, Polanyi believed that society was a natural form designed to provide material sustenance for its members … The new apostles of political economy held that market economy could be self-regulating as long as everything was bought and sold without restriction. This led to what Polanyi called 'the fictitious commodities.' Nature, Society, and Humanity entered the market as land, money, and labor; and the traditions that ensured material provisioning for everyone were swept aside" (2009: 4).

To describe the historical transformation to market-directed society and the ideologization of the self-regulated market in the nineteenth century, Polanyi spoke of economic behavior as having become 'disembedded' from the social matrix, partly through the commodification of land and labor. (In this, Polanyi was following Marx's lead on what were the key instigators in the historical transition into capitalism.) Land and labor are closely linked to community and identity; their transformation in the market capitalist era into objects that could be bought and sold, or alienated, like any other commodity, represented a fundamental qualitative shift in human history. Through all prior history, Polanyi argued, "man's economy … [was] submerged in his social relationships" (1944: 46). Under market capitalism, by contrast, "instead of economy being embedded in social relations, social relations are embedded in the economic system" (1944: 57).

The terms embedded and disembedded were to assume far reaching importance, as they were taken up as antipoles not just in economic anthropology, but in economic sociology, political economy, and institutional economics. All these take it as axiomatic that economy is 'embedded' in society and culture, meaning that one cannot make sense of economic phenomena, even seemingly pure or abstract entities as a currency market, without reference to the social, cultural, institutional, political, geographical, and historical context in which one finds them.

Polanyi claimed that the tools, assumptions, and focus of contemporary economics were maladapted for studying preindustrial (and socialist-governed) societies, and perhaps vice versa. He differentiated two aspects of economic study in keeping with these separate tasks: The *formal* approach, suitable for studying decision-making and other means–ends phenomena such as one finds in the market, and the *substantive* approach, which emphasized the role of social norms and the orientation toward basic provisioning in a society (1957). These terms, which are cognates of disembedded/embedded, became terminological banners in a fiery debate between two camps – formalists and substantivists – that carried on through the 1960s.

The substantivists studied the ways in which economy was embedded in social relations and institutions. Their adversaries, the formalists, agreed with economists about the universal tendency toward utility maximization and therefore the determinative role of rationality in economic behavior. The role of the anthropologist, for the formalists, was to peel away the mask of culture and circumstance to show how ostensibly irrational decisions about what to maximize, who to trade with, how to set a price, how to decide what to plant, etc., are in the end rational – so long as one knows what to look for.

The formalist–substantivist debate died more from exhaustion, mismatched objectives, terminological imprecision, and finally the perception of irrelevance rather than through resolution. The opposition between two schools has been replaced by a sometime division of labor, sometime blending of the two outlooks. There is general acceptance that both elements – mutuality and market, in a contemporary iteration – are present in all societies (Gudeman, 2008).

Polanyi's analysis of premarket societies led to refinement of the concepts of reciprocity and redistribution. As Mauss had done when he posited that gift exchange characterized early economy, Polanyi sought to typologize economic institutions in preindustrial societies so as to contrast them with how market-dominated societies were organized. He settled on reciprocity and redistribution as being the fundamental, representative building blocks of primitive and archaic social organization, respectively. Reciprocity described mutual or symmetrical exchanges, such as between kinsmen, while redistribution took place hierarchically, such as when a chief collects wealth and then reallocates it in accordance with social divisions.

In *Stone Age Economics* (1972), Marshall Sahlins extended the analysis of reciprocity and redistribution. Aiming to show how exchange relations underwrite social relations, which is exactly Polanyi's point, Sahlins defined three kinds of reciprocity: (1) *Generalized*, corresponding to a western notion of a pure gift, in which "the social side of the relation overwhelms the material and in a way conceals it … the expectation of reciprocity is left indefinite" (1972: 206). (2) *Balanced*, in which an equivalent return is made right away, as in trade, and "the material side of the exchange is as important as the social" (1972: 206). (3) *Negative* reciprocity, which is the attempt to get something for nothing, like theft.

Sahlins proposed the following diagram (**Figure 1**) to show how kinship distance is associated with reciprocity, and he cites ethnographic instances to support his typology. The diagram is not intended to be static. One can trade with hostile neighbors, for instance, with the intention of creating a peace pact with them, thereby altering the social relation to a 'friendlier' sort (from negative to balanced reciprocity).

After *Stone Age Economics*, Sahlins distanced himself from nomothetic propositions of this sort, preferring to show how economies were rather structured by local symbolic or cosmological schemes (1976, 1988). Nevertheless, his theory of reciprocity inspired many economic anthropologists of the time and the model improved our understanding of exchange dynamics even in industrialized society. The concepts of reciprocity and redistribution continue to be refined and modified through contemporary ethnography (see, e.g., Davis, 1992; Hunt, 2002; Woodburn, 1998). With the recrudescence of market fundamentalism and the rise of neoliberalism since the 1980s (Harvey, 2005), Polanyi's ideas seem to be getting quite relevant again (Hann and Hart, 2009, 2011).

Modes of Production, Articulation, and History

Prior to Malinowski, anthropologists tended to equate economy with technology. They regarded the stage of technological development in how a given society procured the material means of its subsistence, or its mode of production, to be the defining feature of its economy. The mode of production would either be determinative of other kinds of social relations (division of labor, political organization, family structure, law, etc.) or at least it would correspond with those relations in a way that could be classified and compared.

Modes of production (MoP) flowed from simple to complex forms, implying historical or evolutionary stages. There were four principal divisions: hunter-gatherers, horticulturalists and pastoralists, peasants, and industrial societies. It was recognized even from the outset that this ordering was comprised of ideal types only, since empirically reported overlaps were often marked enough to place the classification at risk of murkiness. Particularly, the question of what is peasantry was debated at great length.

Nevertheless, there were certain features ascribed to societies thus classified such that the division appeared to remain useful for purposes of data collection and analysis at least through the 1960s. After that, the traditional typology became muted or transformed. With the perceptibly increasing speed with which capitalism and other exploitative forces were penetrating remote sectors of the globe, the traditional predilection for studying isolated unit societies – and the fiction that there indeed ever were such places – gave way to the pursuit of illuminating one-world interconnectivity, historically and contemporaneously.

Thus opened a new frontier of research in the 1970s, likewise centering on MoP but reorienting that term with a decidedly Marxist slant. Marx had long been recognized (if not always acknowledged) as a foundational influence in anthropology (Bloch, 1983). In American anthropology in particular, various streams of materialism resonated with Marxist premises (Sahlins, 1976). When on that side of the Atlantic world systems analysis and dependency theory – branches of political economy outlining the historical processes whereby poor countries became victims of rich ones – opened up, they became a ready magnet for economic anthropological investigation.

The new school, led by figures such as Eric Wolf and Sidney Mintz, likewise operated under the Marxist umbrella while partially sidelining Marx's teleological historical materialism. Wolf took the lead when he elaborated a new scheme of MoP, which, after Marx, he defined as "a specific, historically occurring set of social relations through which labor is deployed to wrest energy from nature by means of tools, skills, organization, and knowledge" (1982: 76).

For Wolf, MoPs were not neutrally occurring patterns that one could describe as if making sense of an organism or an engine (metaphors that had inspired structural functional analysis in anthropology) but they were suffused with power. There were exploiters ('surplus takers') and exploited (producers, laborers) in every economic system. A first purpose of MoP theory was to expose the systems of exploitation characterizing different types of society. Sometimes this exploitation took the form of gender inequalities or those attributable to age. Other times it was a ruling elite or a class of landholders. Not altogether divorcing himself from the older classifications outlined above, Wolf specified three MoPs – kinship, tributary, and capitalist – each of which, again, encompassed its own form of political organization, morality, and rituals that, this time, were seen in terms of their serving to justify existing power relations.

The second objective behind the MoP idea was to describe the process whereby the capitalist MoP either existed asymmetrically alongside other kinds of MoPs or brought about their conformity to the capitalist mode. The term used for this was 'articulation.' The intellectual center of gravity for this work was in France. Claude Meillassoux, Emmanuel Terray, Pierre-Philippe Rey, Georges Dupre, Maurice Godelier, and a handful of others, known as structural Marxists because they drew inspiration from Marx and Levi-Strauss, invented their own variant of MoPs to explain economic power relations. They asked, how might Marx's theories apply to contemporary noncapitalist societies? Their method was ethnographic rather than historical, a viewpoint which allowed them to better get at the synchronic fact that the capitalist MoP did not simply drive other types out but could coexist and 'articulate' with them. The work of this group was both empirically and theoretically inventive, and, despite the more than occasional abstruseness of the writing, achieved something of the status of an intellectual fad among anthropologists in the UK and America in the 1970s, before quickly fading (see Nugent, 2007).

The anthropological literature concerning production, labor, work, and related concepts, in relation to world capitalism or in more limited terms, began to flourish during the 1970s. Considerable attention was applied to what the relevant units of production might be – household, lineage, occupational group, factory, etc. – which led to detailed analysis of the economic and social organization within those units. The articulation phase of studies bequeathed economic anthropologists a greater latitude of thought concerning the possible coexistence or hybridity of different MoP – firms and families (or capitalist and kinship), for instance – and how individuals and groups may strategize to shift among these to protect both their livelihoods and their values.

Ethnographic studies of division of labor according to gender (e.g., Nash and Fernandez-Kelly, 1983) were among the most fruitful outcomes of the focus on production. Gender studies of labor have yielded many insights, from the imbricated constitution of domestic and economic spheres, to power relations in the control of the products of household labor, to the gender-mediated enabling mechanisms of post-Fordist flexible accumulation. While the stereotypic view is that production was a fascination in the 1970s that gave way to consumption, the ongoing efflorescence of ethnographies illuminating the micro characteristics and macro consequences of gendered labor, from villages to advanced industrial settings, emphatically belies this view.

Consumption, Agency, and Meaning in Modern Economy

The rise of interest in consumers and consumption took place in the fields of history, sociology, anthropology, and marketing studies at about the same time. In anthropology, there were three books in particular that may be cited as the birth moments: Mary Douglas and Baron Isherwood's *The World of Goods: Towards and Anthropology of Consumption* (1978), Pierre Bourdieu's *Distinction: A Social Critique of the Judgement of Taste* (1984), and Daniel Miller's *Material Culture and Mass Consumption* (1987).

In hindsight, the growth of the anthropology of consumption seems self-evidently tied to the triumph of neoliberalism and its ideological linking of consumption to economic prosperity starting in the 1980s. It can also be related to the disappearance of ethnographers' traditional field sites – the remote locales where manufactured consumer goods had had little sway. If the effects of wage work, cash crops, and other capitalist structures in African or Latin American villages had been visible for decades, it was not until the 1980s that anthropologists found in these same places the diffusion of consumer goods familiar to them from home. A new line of questions opened up: Can mass-produced consumer goods be vehicles for distinctive cultural expression, as locally produced objects are? What are the economic and social consequences of their importation to these locations? Is there a natural demand for such goods, or do native peoples adopt them as a consequence of some form of persuasion?

Up to that point, anthropologists had taken consumption either as a factor of production (i.e., as an input to the reproduction of producers, with a consequent emphasis on food) or distribution (i.e., that goods were apportioned on the basis of kinship, clan, etc., and this, rather than how individuals conceived of the goods, stamped their meaning). The state of affairs in industrialized society, moreover, was not of interest to most ethnographers, who infrequently conducted fieldwork in such settings.

The World of Goods extended symbolic anthropology to economic concerns within anthropology. Anthropologists had long interpreted local cosmologies through objects, known as material culture studies, but mass consumer goods as such had lain beyond the scope of these studies. Douglas and Isherwood argued that consumer goods could be understood as a semiotic code that reflected and stabilized social positions and cultural categories (see also Sahlins, 1976) and as such could be studied the same way everywhere.

Pierre Bourdieu (1984) operated from a comparable assumption, but added empirical and theoretical sophistication through a framework that showed how individual acts of classification through consumption, or the exercise of taste, is a form of social action that produces and reproduces objective social categories, most importantly class.

In reflection of these ideas and those deriving from his native discipline of archaeology, Daniel Miller (1987) devised a new synthesis that became the dominant approach to anthropological consumption studies. Miller

aimed to dispel what he regarded as a false prejudice promoted in the work of the Frankfurt School and French neoMarxists such as Jean Baudrillard. These theorists argued that just as capitalist production had in an earlier phase of capitalism been built upon alienating workers from their labor and from the tools of production, in the present era consumption had become the principal vehicle for alienating individuals from themselves and from culture. Miller emphasized "the potentially active role of consumers in resocializing commodities" (1995: 144). He contended that Marxist 'discourses about consumption' had to be distinguished from actual practices, which could only be studied ethnographically.

The proliferation of consumption studies, driven in part by the demographic expansion of the discipline during the 1980s and 1990s (just when the most consumerist generation in history was coming of age), has attracted formidable critiques. Many dispute the extent to which consumers are able to 'creatively recontextualize' mass commodities and make of them wholly distinctive individual and cultural identities, as Miller and his followers argue. They claim that consumption studied in this way overemphasizes individual agency in a world where the rise in consumption as a paradigm for prosperity has contributed to greater inequality and the attrition of time and monetary resources available to households for noncommercialized use (Carrier and Heyman, 1997). Cultural agency through the recontextualization of material objects may be exercised even by slaves; consumer agency requires purchasing power.

Others have demonstrated that the attempt to understand consumption independently of the powerful imperatives of capitalist production, historically and contemporarily, can only be partial (Mintz, 1985). Ethnographic focus on corporate marketing reveals the influence of consolidating industrial consortiums (such as in food, medicines, finance, energy, tourism, and media) that mobilize state-sized budgets and strategic planning apparatuses to secure hospitable cultural and infrastructural circumstances for the trade of their products globally. Their procedures are best seen not so much as efforts to commoditize (or brand) objects and convince people to buy them, as to move people themselves, with the help of distribution channel management and consumer education campaigns, into prefabricated commodity zones. As marketing has broadened since the 1960s, social sector assets have been vastly commercialized, communal and environmental protections diverted, and consumer consciousness, if hardly captured, has nevertheless been considerably swayed toward the internalization of commercially-mediated archetypes for materializing identity ('lifestyle') and achieving happiness (Applbaum, 2003, 2009).

Transitions to Modern Economy

Economic anthropology came of age just as the capitalist mode of production and world market was lapping its tongue into the last remote corners of the earth, where anthropologists had only recently arrived. The discipline has devoted much attention to how these transitions are experienced and accommodated by non-Western peoples.

In 2000, the French social theorist, sociologist, and anthropologist, Pierre Bourdieu, reflecting upon his fieldwork in Algeria in the 1960s (but surely with the present market fundamentalist turn in mind), wrote: "The principle of the overturning of the vision of the world in late colonial Algeria was nothing other than the acquisition of the spirit of calculation … To subject all the behaviours of existence to calculating reason, as demanded by the economy, is to break with the logic of philia, of which Aristotle spoke, that is, the logic of good faith, trust and equity which is supposed to govern relations between kin and which is founded on the repression, or rather the denegation, of calculation" (2000: 25).

If at the back of much economic anthropological theory lays a debate with economics, including over whether calculative rationality is a cultural–historical artifact or a universal caste of mind, the afflatus of the discipline's empirical work has often been to make sense of the effects on individuals, families, and communities of the broadening and deepening of capitalism. A dismal light often illuminates these studies because the observed reality from anthropologists' standpoint is that the impact of capitalist expansion is frequently deleterious to the lifeways and life chances of the economically humble.

Early studies of the transition to market society, so conceived, tended to be categorical and vectorial. Bohannan and Dalton (1962) described three types of local African economies: marketless, peripheral markets, and market-dominated. The economic characteristics of each were enumerated in terms of the principal source for subsistence livelihood, price formation for goods, money and money uses, external trade, and technology. The three types stood in a historical relationship with one another, with the implication of unidirectionality.

In an influential paper called 'The impact of money on an African subsistence economy,' Bohannan (1959) described the Tiv in Nigeria as having 'a multicentric economy' with mutually exclusive spheres of exchange. These separate spheres, which consisted of subsistence goods, prestige items, and rights in human beings, were "marked by different institutionalization and different moral values" (1959: 124) and were transacted with 'special purpose monies.' When the Tiv came to be forced to pay taxes in coinage, Bohannan said, they had to go about acquiring it through involvement in market transactions outside of their tribe. They started growing cash crops and thus became ensnared in the supply and demand system of distant trade. With this came the decline of special purpose money and its replacement with unitary currency, or 'general purpose money,' like dollars, which act as a unitary standard of value and can in theory exchange anything for anything. The breakdown of the multivariate economy, Bohannan lamented, spelt a decline in the traditional morality embedded in Tiv economy.

Today, Bohannan's depiction carries the air of a just-so story: factually dubious and theoretically simplistic. "It is not clear that money always flattens social relations, rather than creating new ones just as complex," Bill Maurer comments (2006: 21). And of course, market societies are themselves replete with 'special purpose' currencies such as store coupons, subway tokens, gambling chips, and even online virtual worlds money, not to mention myriad forms of nonmonetized exchange. (Spheres of exchange are still taught to

undergraduates because they broaden the minds of those unaccustomed to the thought that there were once societies where most things were not exchangeable for just anything else at a monetary price.)

Speaking just of money, early schemas like Bohannan's yielded to rigorous and sophisticated analyses of money's history, uses, and significance (Graeber, 2011; Guyer, 2004; Hart, 2001; Maurer, 2005; Parry and Bloch, 1989). Some of these still marginally concern themselves with the tensions associated with grand economic transitions (e.g., financialization, securitization, and depersonalization), while others resist or ignore this issue to focus on matters of purely local complexity. In either case, the accomplishment of the sub-subfield ('the anthropology of money') at least since the 1980s is hardly contingent on this narrative.

At present, the broadest umbrella under which economic transitions are studied in anthropology concerns neoliberal restructuring, referring to policies enacted upon the belief that the market is always superior to the state at managing and distributing public resources. Sometimes the procedure is called 'rolling back the state.' The trend in many places since the Reagan–Thatcher revolution has been toward the diminishment of the state's role in providing for health, utilities, education, environmental protection, and social insurances.

Case studies addressing themselves to the differing effects of and adaptations to neoliberal policies provide a rich corpus from which to compare outcomes and formulate generalizations. One key point where anthropological analysis of these trends is concerned is that inspection of them at the register of the local reveals aspects that are rarely discerned from afar. Few ethnographers neither end up endorsing unidirectional or unidimensional frameworks, nor do they invariably find that the decline of traditional economies always results in changes for the worse (Ensminger, 1992). Ground-level analyses show how macro-level terminologies (proletarianization, marketization, and trade concentration) are at best incomplete without reference to how these are experienced by individuals, families, communities, networks, institutions, and the culture-specific moralities that animate them.

History may prove that the long-term trend is as Bourdieu sketched for Algeria. There is benefit in any case to theorizing the processual mechanisms by which alterations in the fabric of economic consciousness conform to and actuate economic realities. Most anthropologists involve themselves with shorter range analyses, and at this level 'great transformation' schemes may be more diverting than helpful. At the axis point (the moment of articulation) of large systems, one finds economic actors operating "in the ambiguous boundaries between capital and labor, cooperation and exploitation, family and economy, tradition and modernity, friends and competitors …" (Smart and Smart, 2005). In many places, globalization has not cemented the role of formal capitalist institutions, but the reverse has occurred (Hart, 2012). A close look at entrepreneurs in many places reveals the contradictions of lives lived half in the local moral world of the village or tribal community and half in the aspirational world of the global market with its characteristic rationalities.

As ethnographers, anthropologists can observe the disruptions, ambiguities, and contradictions associated with economic change and stability (remembering that stasis is a social process). As global comparativists and long-range historians, anthropologists are well situated to track revolutionary changes as well as patterns of stable diversity in economic organization.

Underwriting and mediating the ruptures and continuities associated with economic change of whatever sort is the work of culture. Economic anthropologists have always minded the involvement of worldview, religion and cultural representation in their account of production, exchange, and so on. Starting particularly in the late 1970s, when symbolic and interpretivist anthropology crystallized into a permanent force in the discipline as a whole, a 'cultural economic' approach became more distinct (see, e.g., Geertz, 1979; Gudeman, 1986).

A signal culturalist position written in response to the world systems approach in anthropology (e.g., Wolf, 1982) is formulated by Sahlins in the following quote, which can suitably bookend that of Pierre Bourdieu at the opening of this section: "Western capitalism has loosed on the world enormous forces of production, coercion and destruction. Yet precisely because they cannot be resisted, the relations and goods of the larger system also take on meaningful places in local schemes of things. In the event, the historical changes in local society are also continuous with the superseded cultural scheme, even as the new state of affairs acquires a cultural coherence of a distinct kind. So we shall have to examine how indigenous peoples struggle to integrate their experience of the world system in something that is logically and ontologically more inclusive: their own system of the world" (1988: 10).

Contemporary Futures

The history of the development of research themes in economic anthropology has largely been one of accretion rather than replacement. Growth has been catalyzed in response to new (or newly perceived) developments in world economic circumstances, and in dialogue with neighboring disciplines.

In addition to the continuation of traditionally-themed studies, as described above, in the late 1980s economic anthropologists began to take seriously the challenge of interpreting economic affairs beyond the scope of the village or town. (Anthropologists focusing on development achieved this enlightenment sooner; see Edelman and Haugerud, 2005.) First, the study of the cross-border movement of various types of objects, from craft goods to coffee, was identified as a useful way to grapple with the complexity of trade in both historical and contemporary economy. Much was learned about both cultural brokerage (cultural economy) and power relations (political economy) in such studies. At the same time, ethnographies of assembly plants in places such as Mexico or Malaysia linked in the labor conditions and the circumstances for export of manufactured commodities across commodity chains owned and organized under capitalist enterprise.

For some, the fascination with commodities expanded to include goods such as textiles, cellphones, and pharmaceuticals, whose intellectual patents and process management reside in industrialized countries and are reckoned as exports when they are sold elsewhere. Anthropologists studying these transactions were, whether they were cognizant of it or not,

responding to corporations' own recognition that developing countries were no longer important just as a source for material inputs or cheap labor, but as markets for their products. Some anthropologists went further and studied intermediary institutions, such as bottling plants, shopping centers, or advertising agencies, in urban centers in Thailand, Srilanka, or Trinidad, in the attempt to get at questions of cultural translation and power at the sites where these are ostensibly brokered.

Since the 2000s, a handful of economic anthropologists have surmounted the challenge of access and have rendered fascinating and complex ethnographies of economic institutions at the geographical, institutional, and informational 'cores' of capitalism – New York, London, or Tokyo, for instance. Banks, stock markets, global consumer goods corporations, as well as development agencies and nongovernmental organizations, have each been the focus of recent works.

The aim to engage capitalism on its home turf (bearing in mind that capitalism, like democracy, is hardly an unalloyed system; anthropologists sometimes speak of capitalisms) corresponds with a belief among some that the discipline ought to be seeking greater relevance to current world events. The financial crisis of 2008 in particular sparked reflection on this matter. In the immediate aftermath of the events, Hart and Ortiz (2008: 2) wrote, "It seems that, along with the bankruptcy of some banks and even countries, the delegation of the power to channel credit to the private bureaucracies of contemporary finance has already lost its air of inevitability and indeed its former legitimacy … [W]e need to devise new global institutions and to think about them in fresh ways … Do anthropologists have something to say about all this?"

James Carrier, editor of the *Handbook of Economic Anthropology* (2012), reconvened the contributors to the recent first edition to update the volume to account for the recent economic turmoil, with a view that readers both in and outside the discipline might benefit from how economic anthropologists were making sense of what had happened. One of the contributors, the anthropologist and anarchist intellectual David Graeber, is credited as one of the inspirations behind the Occupy Wall Street Movement; his 2011 book, *Debt: The First 5000 Years*, is crafted as a conceptual and political antidote to current financial arrangements.

In 2012, President Barak Obama nominated Jim Yong Kim, an anthropologist, to the presidency of the World Bank. Kim is a medical rather than economic anthropologist, but his 2000 coedited book, *Dying for Growth: Global Inequality and the Health of the Poor*, is in tune with the conclusions of many studies by economic anthropologists involved in development. The relationship between economic anthropology and medical social science has been quietly blossoming as professionals in global health and related fields have come to recognize the ascendant role neoliberal market reforms have come to play in health care delivery and medical technology development and use.

The unofficial leader of the movement to catapult economic anthropology into public debate about the economy is Keith Hart. Citing the Nobel Prize winning economist Ronald Coase who said in 2012 that "the project of economics needs to be rescued from the economists," Hart and his associates have named their project at the University of Pretoria, the Human Economy Program.

In studying capitalism and its consequences, anthropologists have conventionally paid heed to inequality. The belated eruption of concern over degradation of the environment and the depletion of natural resources – resulting from our current economic system's desideratum to expand – may lead to a shift in the discipline's emphasis toward questions of sustainability (e.g., Wilk, 2010). This focus would inspire renewed associations with ecological/environmental anthropology. It may be that not just the future of the tiny subdiscipline of economic anthropology stands to benefit from these worldly engagements.

Abstract

Economic education focuses on identifying and developing teaching and research techniques that make economics more accessible, relevant, and applicable to both students and educators. The field offers a strong and diverse group of organizations that encourage and promote economic education. This article offers an overview of those organizations, as well as of the content that is typically covered in economics courses, the teaching methods used to teach that content, and the assessment of students and instructors.

Introduction

As a discipline, economic education focuses on identifying and developing teaching and research techniques intended to make economics more accessible, relevant, and applicable to both students and educators. Current efforts in economic education concentrate on continuous improvements related to the following topics: organizations, content, teaching methods, and assessment. Comprehensive reviews on teaching and learning economics, as well as on economic education research, can be found in Hoyt and McGoldrick (2012). The *Journal of Economic Education* is the leading academic journal in the field.

Organizations

Since the beginning of the twenty-first century, the number of local, national, and international organizations devoted to economic education has increased dramatically and the focus of those organizations has shifted to emphasize financial literacy in addition to economic education. Long-established organizations, such as the Council for Economic Education (formally, National Council on Economic Education) and its Council/Center network, continue to deliver programs and promote economic education at the local, state, and national levels. Other organizations, such as the Federal Reserve, have expanded their public relations mission to include economic education for both adult and K-12 audiences. Indeed, the primary focus of several Federal Reserve branch banks has become economic literacy, and the Federal Reserve makes extensive resources available online through www.federalreserveeducation.org. These initiatives are the result of direction from the Chairman of the Federal Reserve, and local needs (Bernanke, 2013). Likewise, the Jump$tart Coalition and other organizations have expanded their programming to include teacher training and other educational activities (Jump$tart, 2013).

Since 2007, and the economic turmoil that resulted from upheaval in financial markets, there have been additional calls for increased economic literacy generally, and an increased focus on financial literacy and wealth management, specifically. At the federal level, the passage of the Dodd–Frank Wall Street Reform and Consumer Protection Act resulted in the creation of the Consumer Financial Protection Bureau, which has economic and financial education as one of its core functions (Dodd-Frank, 2010). What form that function will take and how it will affect economic education has yet to be determined (CFPB, 2013). Given its broad mandate and budget, however, that impact could be significant.

Organizations focused on economic literacy have moved beyond policy statements and have made considerable progress in both implementing economics into the precollege curricula and developing mandates for economic education. These mandates vary by state and range from simple inclusion in the K-12 curriculum, to required coursework, to summative testing prior to graduation. The greatest strides in curriculum implementation occurred between 1998 and 2000 with the number of states requiring economics in the K-12 curriculum rising from 38 to 48; as of 2013, all 50 states require economic content. From 2000 to 2011, the number of states requiring K-12 students take an economics course rose from 13 to 22. Additionally, the number of states requiring testing in economics has fluctuated over the years, with 22 of them requiring testing in 2000 and 2011 (CEE, 2011).

The question raised by Siegfried et al. (1991) as to whether economic education is achieving the goal of having students 'think like economists' is still very much unanswered. Despite the dramatic increase in resources and attention devoted to economic education, the gains in economic understanding are illusive and difficult to measure. Recent research documents only marginal gains in economic understanding in voluntary student samples between 2000 and 2009. Furthermore, the observed gains may be attributable to differences in incentives and testing format (Butters and Asarta, 2011). Whether this is due to increasing enrollments resulting in less-proficient students taking economics courses, deficiencies in the ability and human capital of teachers, or some other factor is unknown. What is clear is that the mission of the various organizations promoting economic education is not complete, and their work remains unfinished.

Content

The study of economics examines how individuals, organizations, and societies make choices under conditions of scarcity. Thus, a primary goal of economic education is to equip

students with the knowledge and tools they need to make the best choices possible, given the resources available. Unfortunately, recent studies have shown a widespread deficient level of economic knowledge among students and adults (i.e., Markow and Bagnaschi, 2005; Czelusniak, 2009; Butters and Asarta, 2011). These findings, along with recent developments in the world economy, have sparked a renewed emphasis for identifying the economic content and principles that the public should know to be successful consumers, workers, employers, and citizens.

For purposes of developing materials and improving pedagogy, formal instruction in economic education can be separated into six major categories: fundamentals, microeconomics, macroeconomics, international, measurement methods, and social goals. Measurement methods and social goals are often found in the first four categories (Buckles, 1991: pp. 26–27).

Narrower lists of content categories have been used in developing nationally normed, standardized, and reliable instruments to measure economic literacy and knowledge (Asarta and Rebeck, 2012). For example, the *Test of Economic Literacy*, currently in its fourth edition (Walstad et al., 2013), is divided into four content categories: fundamentals, microeconomics, macroeconomics, and international economics. Additionally, the *Test of Understanding College Economics (TUCE)*, also in its fourth edition (Walstad et al., 2007), is further divided into two broad categories: microeconomics and macroeconomics. For the TUCE, fundamentals are included as part of the microeconomics content, while international economics is infused in both macroeconomics and microeconomics.

Valid and reliable tests of economic knowledge and literacy can serve as a reference for the content that is covered in macroeconomics and microeconomics. Historically, macroeconomic content has focused on (1) national income accounting, (2) real versus nominal values, (3) investment and saving, (4) money demand (liquidity) and money supply, (5) aggregate expenditure (demand) and supply, (6) stagnation and growth, and (7) monetary and fiscal policy. For microeconomics, the content has focused on (1) scarcity and opportunity costs, (2) demand and supply, (3) market failures and externalities, (4) revenue, cost, and profit maximization, (5) market structures, and (6) equity and efficiency (Becker, 2001).

Economists have argued that the best way to prepare students for their futures is to focus on a reduced list of core topics, instead of attempting to cover every topic found in principles textbooks. In fact, McConnell (1998: p. 41) suggests that in order to avoid barriers to learning, which may result from cognitive dissonance, instructors should be selective and introduce economics concepts using broad topics that are accessible to the student. In microeconomics, Frank (2012: p. 405) provides the following list of essential principles: (1) scarcity, (2) cost–benefit, (3) comparative advantage, (4) increasing opportunity cost, (5) equilibrium, and (6) efficiency. Frank notes that, while reduced, this list of essential principles is at the root of all other microeconomic concepts. Additionally, Gilleski and Salemi (2012) propose the use of literacy-targeted courses focused on core topics that students will be able to use for the rest of their lives. Literacy-targeted courses differ from traditional courses in that they cover fewer topics more intensively, and provide opportunities, through course assignments, to gain a better understanding of basic economics. In microeconomics, these topics include (1) scarcity, choice, and opportunity cost, (2) comparative advantage, (3) demand and supply, (4) elasticity of demand, (5) price taking and economic efficiency, (6) economic profit and rent, (7) market power and price setting, and (8) externalities and property rights.

For macroeconomics, several economists have suggested additional concepts that are rarely covered in textbooks or standardized tests, but that are critical for citizens since they are found in the daily news or faced in everyday life situations. For example, Kennedy (1992) supplied a list of five key relationships consistently faced by individuals: (1) the discouraged or encouraged worker phenomenon and reported unemployment changes, (2) forecasting of inventories and production, (3) nominal versus real interest rates, (4) inflation rate differences and changes in exchange rates, and (5) the tendency of real interest rates to be equal across countries. Furthermore, McEachern (2012) recommends an even broader selection of topics to underscore in macroeconomics, including automatic stabilizers, long-term joblessness, technological change and living standards, the institutional setting, and the dynamic nature of the economy.

While many economists and organizations have attempted to create lists providing the key economic content that students and adults should know, to date, the economics profession has not been able to agree upon a universal list of skills, abilities, and knowledge needed to become economically literate.

Teaching Methods

The greatest innovations in teaching methods in the past decade have come from the ubiquitous adoption of the Internet and the arrival of students who are 'digital natives,' or students for whom computers and the Internet have been a fact of life instead of a recent innovation. For these students, traditional lecture formats are less satisfying, and do not provide the interactivity and dynamic environment they have come to expect. Thus, instructors have had significant incentives to adopt digital content and delivery (Levin and Arafeh, 2002). As a result, many of the innovative teaching methods first identified in the late 1990s are now being implemented using technology. For example, the prevalence of portable devices that are Internet-enabled makes teaching strategies that engage students immediately prior to class, or 'just-in-time teaching,' low cost and effective (Simkins and Maier, 2004).

Not only has the Internet changed the nature of instruction, it has changed how and when instructors teach. Today, the economics classroom can be a traditional lecture-based classroom, a fully online classroom, a hybrid of the two, or a 'flipped' or 'inverted' classroom. Research into the efficacy of online versus face-to-face instruction, while mixed, has largely concluded that students in a traditional classroom score significantly higher on assessments of economic knowledge than do their peers in pure online courses. This difference becomes insignificant for students in hybrid courses, or courses with some online instruction mixed with traditional teacher interaction (Brown and Liedholm, 2002; Terry et al., 2003;

Coates et al., 2004; Anstine and Skidmore, 2005). Possible reasons for the difference in outcomes for online versus traditional courses include the reduction in student–instructor interaction, limited possibilities for peer instruction, the high fixed costs associated with developing quality online content, and the quality of course management software (CMS) (Goffe and Sosin, 2005). As educators are able to develop better online content, and as CMS systems improve, we would expect the observed deficit in online education to be reduced or eliminated.

An increasingly popular form of course organization, the 'flipped' or 'inverted' classroom, leverages various teaching strategies to fundamentally change instructional flow. In an 'inverted' classroom, the first exposure to new content occurs prior to class via videos or readings available online. Online tests or in-class quizzes are used to incentivize students to complete the 'first exposure' materials. Class lectures and activities are then designed to extend understanding to a deeper level. Finally, homework is used to follow up on and measure learning outcomes.

First identified in a paper published in the *Journal of Economic Education*, the 'inverted' classroom model allows instructors to use class time to engage students in discussion, problem solving, and other active learning strategies that may address some of the long-standing questions in economic education (Lage et al., 2000). For example, a large body of research from the science, technology, engineering, and mathematics (STEM) disciplines suggests that active learning strategies such as 'peer instruction' or 'interactive learning' dramatically increase students' understanding of the material taught. Furthermore, not only do test scores for both male and female students rise when using interactive learning, but also the gap between male and female test scores is eliminated. Additionally, students who are taught interactively are less likely to change majors to a non-STEM field and retain learned information longer (Crouch et al., 2007; Lambert, 2012). The persistence of a gender gap in student test scores, the difficulty of attracting women to the economics major, and the rapid depreciation of economic knowledge are three issues that have been persistent, and troublesome features of economic education (Becker, 2001). The success of active learning in STEM disciplines suggests that there may be a single solution to all the three problems in economics.

Beyond the organization of the classroom, the reduction in the cost of online delivery and the availability of digital content have made it possible for educators to address, in unique and innovative ways, Siegfried and Fels' (1979) comment that "Different students learn economics in different ways. The best teaching strategy provides alternative learning methods." For example, online resources such as Coursera (www.coursera.org) and the Kahn Academy (www.khanacademy.org) provide low-cost instructional content to instructors and students alike. Within economics, instructors have created online repositories of movie scenes and art that teach economic content (Mateer and Li, 2008; Watts and Chineze, 2012). As the availability of such resources grows and their quality improves, the fixed costs of offering an online or hybrid course that can compete with the traditional face-to-face course will fall dramatically, further improving the online educational experience of students.

In response to changes in the classroom and the need for improved teaching and research in economic education, the American Economic Association (AEA) Committee on Economic Education began hosting an annual conference that focuses on teaching economics (at the undergraduate and graduate levels) and research in economic education (including precollege levels). The inaugural conference, held at Stanford University in June 2011, hosted educators from around the world and featured keynote speakers such as Vernon Smith, B. Douglas Bernheim, and John Taylor, all of whom spoke on issues related to economic education and teaching. Research presented at the conference addressed many of the issues associated with integrating technology and the Internet into flexible classroom environments. Cosponsored by the *Journal of Economic Education*, subsequent annual conferences have further raised the profile of economic education and best practices for teaching by publishing the best papers presented at the conference in the leading journal in the field.

In sum, while the concepts taught in economics may not be dramatically changing, the nature of economic education and teaching methods is. Programs such as the AEA Conference on Teaching and Research in Economic Education are vital to developing and sharing new teaching methods that leverage the growing body of educational research to ensure that economic education stays relevant and meaningful to students. Additional training opportunities, such as the teaching innovation programs (TIP) series, may be needed on a national level to incentivize and assist educators to make the necessary changes to their teaching style (Walstad and Salemi, 2011). Instructors may guide and inspire students, make the material applicable and interesting with theoretical tools and examples, and provoke thoughts to stimulate interest that encourages students to appreciate and take to heart the study of economics.

Assessment

In general, assessment is the process of gathering data to assign grades, evaluate the effectiveness of programs, and make changes to increase student achievement. Summative assessment focuses on the achievement of students, while formative assessment provides instructors with feedback that can be used to improve what is being assessed (Miller et al., 2009). Suskie (2009: p. 4) provides four steps needed to develop an effective assessment program. First, clear, measurable expected outcomes of student learning have to be established. Second, students need to have ample opportunities to achieve those outcomes. Third, instructors should determine if their students are achieving expected outcomes by systematically collecting, analyzing, and interpreting data. And finally, practitioners need to use that data to understand and improve student learning.

In economics, the two most commonly used assessment methods of student learning involve the use of free-response (constructed-response) and multiple-choice questions. Both methods have received considerable attention in the economic education literature (Walstad and Becker, 1994; Chan and Kennedy, 2002; Buckles and Siegfried, 2006). Each has its advantages and disadvantages. For example, multiple-choice exams require considerably less time to grade, can cover a larger set of concepts, and are more objective in grading than

free-response exams. On the other hand, multiple-choice exams allow for guessing and may not reach the highest levels of Bloom's (1956) taxonomy. Walstad (2001) offers a useful framework for deciding which method instructors may want to use based on their goals and constraints for a course. Additionally, a valuable discussion on how to create and grade test items can be found in Walstad (1998), for multiple-choice items and Welsh and Saunders (1998), for free-response items.

A test instrument needs to be reliable and valid in order to provide useful information for assessment purposes. Reliability is the ability of test scores to consistently measure student performance. One commonly used measure of the internal consistency of a test instrument used in standardized tests of economic knowledge and literacy is the alpha reliability coefficient. Validity refers to the ability of a test to measure what it is intended to measure. This characteristic can be further divided into content validity and construct validity. Content validity is achieved by making sure that a test instrument covers the appropriate content. This goal could be accomplished by utilizing work references indicating the content to be taught at different educational levels, such as the *Voluntary National Content Standards in Economics* (CEE, 2010), and by consulting with experts in the field. Construct validity refers to the ability of a test to discriminate between those students who know the content and those who do not (Rebeck and Asarta, 2012: pp. 318–319).

Additional sources of information for determining whether students understand economic content include homework and problem sets, classroom experiments, group work, and immediate feedback techniques. In fact, recent technological advances have provided educators with opportunities to receive immediate classroom feedback instead of having to wait until the end of the semester or after a test. Students can now use remote handheld devices, such as 'clickers' and smart phones, to answer questions in class. These systems not only allow for a greater level of student involvement in the learning process, but they also provide instructors with immediate summative feedback that can be used to undertake formative assessment. Additionally, another source of formative assessment that has been proven to be effective in improving student learning is 1-min papers (Chizmar and Ostrosky, 1998). One-minute papers, and their many variations, are used at the end of class periods, or via e-mail, and include a number of questions asking students to share what they learned during a lecture and what they still do not understand. This method, while time consuming given that instructors have to read each student's feedback, allows instructors to assess and react to the learning that is occurring in the classroom.

While the assessment of student performance receives a considerable amount of attention in the economic education field, often, it is the instructors who are evaluated by students on their performance in the classroom. This is particularly true at the tertiary level, where students have a chance, at the end of a session, to share their views and opinions with school administrators by completing student evaluations of teaching (SET). SETs typically focus on the overall effectiveness, communication skills, and mastery of the subject matter of an instructor, as well as on the organization and planning of a course, but do not tend to provide formative feedback to instructors. And although the weights assigned to SETs vary depending on the type of academic institution, administrators consistently use this information to evaluate faculty members annually, determine salary changes, and for promotion and tenure decisions (Becker and Watts, 1999).

Unfortunately, research findings using SETs have been controversial, and often questioned due to statistical shortcomings (McPherson, 2006). Additionally, the recent availability of alternative methods of instruction, such as hybrid or 'flipped' courses discussed above, has been found to influence SET scores and should be taken into consideration when evaluating instructors. Asarta and Schmidt (2010) examined the SET scores of college students participating in an introductory economic and business statistics course offered using a traditional and hybrid formats, and found that SET scores were consistently and significantly marked down in the hybrid format. Since administrators typically use SET scores to compare individual instructors to an average, or for ranking purposes within a department, not accounting for these types of variables could be very costly for instructors.

Conclusion

The field of economic education has continued to evolve over the past decade due to recent developments in the world economy, technological changes, and a desire to improve the level of economic knowledge and understanding of individuals. The field offers a strong and diverse group of organizations that encourage and promote economic education, focusing on the content that should be taught, the teaching methods that should be used, and the assessment of students and instructors.

Economic Evaluations and Electoral Consequences

Abstract

Voters evaluate economic conditions and use these assessments to hold the incumbent government accountable at election time. Voters typically assign credit or blame for the economic situation to the government leader, the president or prime minister, and his or her political party. This assignment of responsibility is easy for voters when the locus of responsibility is clear, but it is made more difficult when institutional or government arrangements diffuse power. In general, evidence of economic voting has been found in democracies around the world.

Introduction

"Who will you vote for?" This question is asked in friendly conversations before elections in democracies around the world. We know much about how voters make their decisions: party identification, ideology, policy issues, candidate characteristics, and evaluations of the incumbent's performance all feature prominently in the voter's calculus. Among the conditions a voter might evaluate that economic evaluations are paramount. In this article, we examine the evaluations of the economy that voters make, and how those evaluations affect their electoral choices. According to classical economic voting theory, when the economy prospers voters tend to reward the government with their votes, but if the economy falters, they tend to punish the government by giving their votes to the opposition. We pursue below this reward–punishment theory of economic voting, as it has been dubbed, along with its variants.

Economic evaluations and voter preferences will be measured via national election surveys of public opinion. We will assess where voters look for the economy – at the past or the future, at their own pocketbooks or the entire nation. An important question concerns how accurately voters see the economy. To the extent they misperceive it, is that distortion due to lack of information or to political prejudice? What do they do politically with their economic evaluations? The answer to that question depends on who they hold responsible for running the economy. The clearer the government is in charge, the more likely voters will reward or punish it.

Many things can blur the link between the economy and the government, such as self-blame for economic misfortune or blaming the boss rather than government policies. Besides attribution of blame, institutions play a role. On the one hand, the impact of economic perceptions can be diminished by the structure of institutions, as when many parties are in the ruling coalition, or when the center of decision making moves away from the national capital to an international one such as Brussels. On the other hand, the economic crisis manifest worldwide today may actually increase the strength of economic voting. We deal with such issues below, focusing on the economy as a valence issue, as an issue dealing with the national good. We aim to show how important these economic evaluations are, aiding the proper functioning of a democracy by holding elected officials accountable.

Economic Voting Theory

In the study of political behavior, many of the research guidelines came out of that classic, *The American Voter* (Campbell et al., 1960). The field of economic voting, as it has come to be called, is no exception. In that pioneering investigation of voting, as measured in national public opinion surveys, they ask the question, "Is a person's economic outlook associated with his (sic) partisan choice?" concluding the answer "is substantially affirmative" (Campbell et al., 1960: 397–399). They go on to assert that incumbent President Eisenhower did draw "a disproportionately large part of his popular vote margin from the economic optimists in 1956" (Campbell et al., 1960: 385, 400–401). Such a finding underlined Key's (1966) more general argument that voters evaluate White House performance, rewarding or punishing the president's administration accordingly at the ballot box.

Broad scientific evidence for this proposition first appeared in Kramer's (1971) work, showing that the president's party won or lost votes in congressional elections, depending on voter satisfaction with the economy. Tufte (1978) extended the evidence to presidential elections, contending that Democratic elections are generally propelled by economic fluctuations, with incumbents held accountable by popular referendum. Fiorina (1981) brought the data focus back to individual voter attitudes, as measured in multiple national election surveys conducted by the American National Election Studies (ANES).

Following Key (1966), Fiorina (1981) claimed that voters rewarded or punished the president and his party retrospectively, based on recent past national economic activity. Kiewiet (1983) expanded on this by demonstrating that these national economic evaluations, "sociotropic" as he called them, were much more important for voters than their own private, pocketbook, concerns. Following suit, Lewis-Beck (1988) took the debate across the Atlantic, in his survey analysis of economic voting in five Western European nations, which evidenced clear economic voting in these democracies. Since this 'survey era' of economic voting research in the 1980s, the field has blossomed. This latter work has mostly raised technical issues, but also occasional challenges to the existence of the basic economic voter paradigm. We explore these matters in what follows.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.93148-9

Survey Research on Economic Evaluations

In their daily lives, individuals routinely evaluate all sorts of economic activity, such as the cost of groceries, the sales tax, the size of their pay check, or the national debt. We can systematically observe how individuals evaluate key aspects of the economic world around them by studying their responses in scientific social surveys. In *The American Voter* (Campbell et al., 1960: 393), they wanted to understand the 'economic outlook' voters held, by measuring "a set of rather general economic attitudes [with] no specific political referent." They developed a battery of eight closed-ended items, four of which are still widely in use, and are offered below (Campbell et al., 1960: 395). As can be seen, they ask the respondent to focus on one of two relevant objects (the family or the country), and one of two time frames (a year ago or a year from now).

> Would you say that you and your family are better off or worse off financially than you were *a year ago*?
>
> Now looking ahead – do you think that a year from now you will be better off financially, or worse off, or just about the same as now?
>
> Thinking about conditions in the country as a whole – Do you think that during the *next twelve months* we'll have good times financially, or bad times, or what?
>
> Would you say that at present business conditions are better or worse than they were a year ago?

These items, or close versions of them, have been regularly included in the ANES, conducted every congressional or presidential election year. See, for example, Lewis-Beck et al. (2008a: 365–389) who, using the ANES, relates such items to presidential vote preference in the 2000 and 2004 United States elections. Similar economic evaluations can be gleaned from election studies abroad, most notably the extended battery in the British Election Studies (Clarke et al., 2004). Further, in almost all European election surveys, a core battery of economic items is available, usually following a form close to that listed above. Lewis-Beck (1988: 44), exploring the economy and elections in Britain, France, Germany, Italy, and Spain, fielded 11 items on economic evaluation. More recent multinational studies look especially at retrospective national economic evaluations, e.g., Van der Burg et al. (2007) and Duch and Stevenson (2008).

In the investigation of economics and elections, a main reason researchers moved away from national macro-economic indicators, and to economic evaluation by surveyed individuals, was to overcome the ecological fallacy. Researchers wanted to avoid faulty inferences about individual voter behavior that might occur if only measures on the nation itself were examined. Of course, this notion rests on the assumption that individual level findings on the economic vote ultimately reflect national fluctuations. Fortunately, they appear to, at least with respect to retrospective sociotropic evaluations. Logically, Nannestad and Paldam (1994: 224) argue that, on average, changing perceptions of the economy should be linked to actual changes in the economy. Empirically, in a thorough study of that question, using eight Danish national election surveys, Lewis-Beck et al. (2013b) show that shifts in the national GDP tightly parallel shifts in the citizens' subjective sociotropic evaluations. Thus, we have the encouraging result that economic perceptions seem well-tied to actual economic fluctuations.

Pocketbook versus Sociotropic Economic Evaluation

Journalists, politicians, and everyday citizens often think that when economics counts in an election, it is because of how it impacts a voter's pocketbook. But this egotropic effect has generally been found to be considerably weaker than the so-called sociotropic effect, whereby what counts is how the voter sees the economy of the whole country. (On US elections, these initial findings are reported Alvarez and Nagler (1995), Kiewiet (1983) and Kinder and Kiewiet (1981). On European elections, see Anderson (2000).) Pocketbook effects are weak partly because citizens, perhaps Americans especially, tend to see personal economic successes as the result of their own hard work rather than stemming from government policies. If sociotropic effects prevail, however, it does not mean that the voter is necessarily an altruist, as is sometimes claimed. As Kiewiet and Lewis-Beck (2011) demonstrate, sociotropic voters might be altruists, believing they should reward the party in power for the running of a good economy. But, they could just as easily be egotists, who think they should vote for the party in power because it is delivering a good economy, which they will benefit from. That is to say, voters are able to see that their economic fate is joined with their neighbors.'

Retrospective versus Prospective Economic Voting

What is more important for the voter: the economy tomorrow or the economy yesterday? Looking at the past, the voter has a chance to evaluate the performance record of the ruling party (or party coalition). But, looking forward, the voter can think about whether there are brighter days ahead. It was Fiorina (1981) who staked out the claim for the superiority of retrospective economic voting. However, Downs (1957) and his followers made a strong case for the role of prospective assessments, with voters giving their weight to party promises. A good deal of research has been done, comparing the effects of the two, in elections both at home and abroad. Perhaps the first study was that of Fiorina (1978), who came out strongly for the retrospective side.

But the literature goes back and forth. See, for example, Clarke and Stewart (1994), who conclude that retrospective and prospective evaluations are of about equal importance. Still, a recent book by Lockerbie (2008) decides that, for US presidential elections, prospective economic evaluations dominate. In contrast, Price and Sanders (1995), in a comprehensive examination of the British case, conclude that prospective economic evaluations are much more important for their electorate. In a current investigation of American presidential elections, Campbell et al. (2010) find only retrospective effects. While the debate over the two time dimensions continues, in practice, we see more and more researchers giving the benefit of the doubt to the retrospective paradigm. An outstanding example comes from the largest economic voting investigation ever (165 surveys and 19 nations), by Duch and Stevenson (2008), who report robust sociotropic retrospective effects.

What Do Citizens Know about the Economy?

The 'economy' is not an attitude, but instead something real in the world. But do citizens see this reality? When they are asked to evaluate its performance, do they 'get it right?' The authors of *The American Voter* thought they did, when they said

> [E]conomic outlook does, through individual perceptions of the economic situation, reflect the 'real' world …. [T]here are significant changes in the national economy, particularly the consumer sector of the economy, which these attitudes foreshadow and reflect. Economic events have an impact on both personal and national components of economic outlook.
>
> Campbell et al., 1960: 394–395

What evidence do we have that voters do 'see' the economy? How well do their subjective perceptions compare to objective conditions? When asked to estimate the rates of unemployment, inflation, and growth, American respondents appear to be most accurate with regard to estimation of the unemployment rate (Conover et al., 1986; Holbrook and Garand, 1996; Lewis-Beck and Nadeau, 2009).

Moreover, the knowledge that American voters do have regarding the economy does not seem either enhanced or dampened, on balance, by the news media. For example, Hetherington (1996) finds that media attention in the 1984, 1988, and 1992 presidential elections does not alter their sociotropic retrospective economic evaluation. This result comports with the work of Haller and Norpoth (1997: 567), who, after their news analysis, conclude that "people are able to draw an economic picture that mirrors that real thing."

The strong link between the subjective and the objective economy seems true at the aggregate level, as well as individual level, of perception. Nadeau and Lewis-Beck (2001) show that an aggregated subjective measure of the economy (based on retrospective sociotropic assessments) correlates highly with several objective macro-economic indicators. In a follow-up study, Lewis-Beck et al. (2013c), looking at about 40 years of ANES data, report that sociotropic retrospective evaluation of the economy is shaped by GDP growth, the stock market, and inflation. In one of the few relevant comparative micro-studies, Duch and Stevenson (2010: 122) decide that "individual perceptions about the volatility of the macroeconomy are reasonably well informed; voters appear to understand the extent to which their economies are subject to shocks from the international economy; and voters who perceive that the variation in the national economy differs from variation in the global economy seem more inclined to exercise an economic vote." In sum, voters, appear to grasp the nature of the economy they live in.

How Economic Evaluations Might Be Distorted

While citizens can see the economy, they do not see it perfectly. In other words, when they look at it, they will sometimes make a faulty evaluation. What are the sources of these mistakes? Error can come from three main sources: group identification, level of information, and political bias. The first source, which we begin with, concerns the possible heterogeneity in the economic response caused by different group attachments. For example, Welch and Hibbing (1992) discovered that men were more likely to be pocketbook voters than women in the 1980 and 1984 elections. However, in a more recent study covering US presidential elections 1980–2004, Kam (2009) finds that there is no consistent pattern of difference in how men and women engage in economic voting. Duch et al. (2000), in their exploration of heterogeneity, located different economic evaluations among those with different experiences or information levels. This leads to the second possible source of distortion, coming from voters with more limited knowledge. With regard to this second source, some voters have more relevant information than others. Godbout and Bélanger (2007) show that more sophisticated voters give different weights to pocketbook and sociotropic evaluations. While such results suggest the possibility of some heterogeneity in economic voting, it should not be forgotten that, by and large, the main effects established by the assumption of homogenous economic voters are overwhelming. In sum, as Campbell et al. (1960: 394) concluded long ago, "[A] characteristic of this economic entity is found in the uniformity of its political consequences for many segments of the population. It cuts across class lines, party lines, and through socio-economic groupings, usually showing in all settings the same relationships to a given political variable."

While heterogeneous economic voters may cause little distortion in the general pattern of economic voting, some argue that a lot of distortion comes from political bias. Put another way, voter partisanship may introduce a conceptual lens into the economic evaluation, rendering more favorable judgments of the economy when their party is in power, and less favorable judgments when they are out of power. For example, if I am a Democrat evaluating the economy under the Obama administration, I will likely rate it more favorably than would a Republican. Such partisan bias can operate, as Kramer (1983) told us. The question becomes how great the bias is, and whether it can be controlled away. In the literature, this amounts to dealing with the potential endogeneity of economic evaluations. Certain critics have argued that partisan bias actually induces the apparent economic voting, and once taken into account will leave precious little evidence to support that hypothesis (Anderson, 2007; Evans and Pickup, 2010).

There have been different responses to this endogeneity claim. Duch and Stevenson (2008), attempt to exogenize the sociotropic retrospective economic evaluation variable, as do Lewis-Beck et al. (2008b). These studies engage, necessarily, in sophisticated econometric argument, including two-stage instrumental variable analysis of panel data from multiple countries, to demonstrate the continued existence of an economic vote. In perhaps the most rigorous of such studies to date, Nadeau et al. (2013) apply an instrumental variables analysis to repeated surveys from 10 European electorates. They conclude that, "economic perceptions appear strongly shaped by the objective economy," (p. 565) and these realistic perceptions go on to sharply influence their vote for or against the government.

In contrast to the foregoing elaborate analyses, Lewis-Beck et al. (2013c), simply regressed sociotropic retrospective economic evaluation on partisan bias (as measured by Republican or Democratic identification), via an extensive

examination of the ANES data. They found (in a large sample) that, while partisan bias was a statistically significant predictor of economic evaluation, it exercised a substantively small effect, and accounted for only a tiny part of the explanation (i.e., the pseudo-R-squared was only 0.02). Overall, then, it seems safe to return to the conclusion that voters, within reasonable limits of error, accurately perceive the economy and act politically on what they perceive.

Who Is Held Responsible for the Economy?

For citizens' economic evaluations to influence their vote, the evaluation must be attributed to a political actor who can be ultimately held accountable at the ballot box. In other words, there must be an attribution of blame or praise from the observed economic performance to a political actor. (Peffley and Williams (1985) have written the seminal theoretical piece here.) In presidential systems, such as the United States, that actor is commonly the president, while in parliamentary systems it's the prime minister. For example, in Germany, with its parliamentary system and coalition governments, the chancellor's party, and not the other coalition party, reaps rewards for a strong economic performance (Debus et al., 2014).

There are times when voters might not hold the incumbent government responsible but rather the previous administration. Take for example the recent economic recession. The financial crisis of 2008, which triggered the global economic recession, began under President Bush's watch, prior to Obama's victory in the November election. The economic challenges continued through Obama's first term in office. In 2012, when Obama was up for reelection, voters recognized that he inherited the crisis from the previous administration, and therefore were more likely to blame Bush than Obama for the continued economic sluggishness. This attribution of responsibility to the previous government rather than the incumbent administration helps account for Obama's reelection despite the state of the economy (D'Elia and Norpoth, 2014).

While many voters attribute responsibility for the economy to the political leadership, sophisticated voters understand that the economy is complex and influenced by many actors. The legislature, the central bank, government agencies, private enterprises, investors, and workers all drive the national economic engine. Indeed, some work has shown that the more knowledgeable the voter, the more likely he or she is to assign economic responsibility to some institution other than the presidency or government (Gomez and Wilson, 2003; Hellwig and Coffey, 2011). Additionally, multiple levels of government can cloud responsibility assignment. Such is the case in federal, as opposed to unitary systems (Stein, 1990), or when countries belong to supra-national institutions such as the European Union (Lobo and Lewis-Beck, 2012; Magalhães, 2014). Still, voters, rightly or wrongly, largely attribute responsibility for managing the economy to the national government and its leaders.

But, even this principle, that the president is the economic CEO, has been increasingly challenged by the realities of globalization. The economies of certain countries are heavily dependent on international trade, which means that what is happening in foreign markets directly impacts their domestic economies. In an important cross-national study, Fernández-Albertos (2006) shows that the greater the role of foreign trade, the weaker the attribution of economic responsibility to the national government. Writing more generally, Hellwig and Samuels (2007) find that with more open economics, the economic vote diminishes. As the world becomes ever more connected, the locus of economic responsibility may continue to shift away from the domestic central authorities, rendering the economic vote a more elusive target.

Institutions and the Economic Vote

The economic vote takes place in virtually all democracies. But that does not mean it has the same effect everywhere. We have already seen that, as attribution of economic responsibility varies, the economic effect can vary. However, attribution implies an individual psychological mechanism, operating in different ways across people. Besides individual variation, there can also be institutional variation, from one democracy to another. We have already mentioned, for example, that economic voting may work differently in a federal system, as opposed to a unitary one. There are other institutional arrangements that differ across nations that are still more important, and can influence the magnitude of the economic vote. In their path-breaking study of multiparty democracies, Powell and Whitten (1993) demonstrated that as coalitional governments became more complex, the impact of the economic vote was reduced. Why? Because things such as a greater number of coalition parties makes the line of responsibility for economic policy less clear. Anderson (2000), in a later coalitional study, demonstrates that, in addition to number, party size and unity also matter.

Certainly, institutional features can vary within a country, as well as across countries. Take the popular issue of divided government, where one party controls one elected body, and another party another elected body, e.g., the US president is represented by one party, and the US Congress by another. Norpoth (2001) found that, given such a division, the economic vote remained unaffected, for voters continued to hold the president responsible for the economy regardless. But, in France, divided government gives the economic vote a different outcome. According to Lewis-Beck and Nadeau (2004), under a French unitary government (the president and the prime minister from the same party coalition), the economic vote stands strong, but weakens under cohabitation (the president and the prime minister from different parties). Such examples suggest that the economic voter reasons carefully about who holds the economic reins, as he or she sorts through the labyrinth of institutional rules governing policy and election.

Observing the Economic Crisis

Since the Great Recession of 2008, public attention has been focused on what has come to be called the 'economic crisis' and its political consequences. With respect to the United States, it

appears that the resulting job losses had a clear effect on the presidential vote (Margalit, 2011). Arguing more generally, Campbell (2010) says the Great Recession secured Obama's victory in 2008. With respect to political effects in Europe, several useful article collections have appeared, the first being that of Escobar-Lemon and Whitten (2011), who provide a useful mapping of effects. A subsequent collection addresses the crisis in the European periphery, especially the hard hit nations of Southern Europe (Lewis-Beck et al., 2012). Most recently, an omnibus collection of 26 papers confronts the economic crisis and the vote in democracies worldwide (Lewis-Beck and Whitten, 2013). In those investigations, the classical economic voting theory of reward–punishment generally sustains itself. Furthermore, voters accurately perceive an economic crisis exists, meaning once again that their perception accords with objective conditions. Also, more heterogeneity of economic voting is in evidence, with group effects from class and income observed in some countries.

A lively question concerns whether the economic vote has become stronger, as a result of the crisis. The papers on Southern Europe seem to give a positive answer. For example, in Greece, Italy, Portugal, and Spain, the impact of retrospective sociotropic economic voting seems stronger, when compared to a sample of Northern European democracies (Lewis-Beck and Nadeau, 2012). However, other observers have argued that, despite crisis conditions, the economic vote remains muted. (About this point of view, for Germany see Anderson and Hecht, 2012; for Ireland, Marsh and Mikhaylov, 2012; for the United States, see Holbrook, 2012.)

This contention has also arisen for the Spanish case, which has suffered greatly as a result of the economic crisis, and illustrates well certain dilemmas and solutions. In Spain, almost everyone after the crisis saw the economy as 'bad,' but it was very difficult to detect an economic vote in routine surveys. This condition poses a methodological artifact – the "restricted variance problem" – making it almost impossible to uncover obvious economic voting effects. This difficulty can be solved with the introduction of time, via pooled cross-sections and panel data, whose analysis reveals strong economic voting effects in the 2008 election, and still stronger ones in the 2011 election (Fraile and Lewis-Beck, 2014). In conclusion, in Spain and other countries hard hit by the crisis, economic voting is at least as strong, and perhaps stronger, than before the crisis. The crisis, then, did not make economic voting go away. Instead, it allowed it to operate full force.

Other Sorts of Economic Evaluations

Thus far, our stress has been on sociotropic economic evaluations, where citizens assess the performance of the national economy. With respect to voting, these sociotropic evaluations are regarded as *valence* issues, i.e., an issue where voters hold a consensus view. In this case it means that voters all regard economic prosperity as a good. And, following the classic reward–punishment theory, when they perceive this prosperity, the will tend to vote for the government. Hence, economic voting theory becomes incumbency oriented. But, it might also be policy oriented, as Kiewiet (1983) sagely observed some time ago. In this situation, the citizen votes on the basis of economic policy. For example, a US voter may believe that the democrats offer better unemployment policies and thus will always vote Democratic, regardless of whether or not a Democrat is in the White House. Wright (2012), in a current study, finds that, in fact, rising unemployment always benefits the Democratic party, regardless of whether they are in office. Thus, economic voting becomes positional rather than valence, and is directed at party policy rather than party incumbency. Turning to Western European countries, Dassonville and Lewis-Beck (2013) offer a contemporary exploration of the effects of rising unemployment in the context of policy oriented, rather than incumbency oriented, economic voting.

In his seminal paper, Stokes (1963) was the first to note the distinction between the economy as a valence issue and the economy as a positional issue. In the vast literature on economic voting, almost all of it assumes the valence perspective. But, as Lewis-Beck and Nadeau (2011) have argued, there is room in economic voting theory for the role of positional issues. These positional issues usually can be arrayed left to right, and sort voters on economic policy matters such as unemployment, progressive taxation, market regulation, or industry nationalization. A recent study of the British General Election afforded the opportunity to directly compare valence and positional economic evaluations, and their impact on vote choice. It was discovered that position, measured as preference for progressive taxation, had almost the same effect as valence, measured in the usual sociotropic retrospective way (Lewis-Beck et al., 2013a). In a current examination of the German case, where positional and valence economic voting are systematically compared, they find strong effects for both, with a nod to the valence component (Clarke and Whitten, 2013). Obviously, expansion of the economic voting paradigm to include positional issues would have benefits, especially as it taps into the growing interest in income inequality and its political consequences.

Summary and Conclusions

In this article, we have explored specific investigations of economic evaluations and their electoral consequences, as they have been carried out in scientific survey research at home and abroad. A review of these investigations illuminates the vast terrain of economic voting work, which now numbers over 500 books and articles. With such a large body of work, review essays such as this can be helpful. But no one review essay serves as the be all and end all. We would also like to recognize other available reviews, Duch (2007), Hellwig (2010), Lewis-Beck and Stegmaier (2000, 2007, 2013), Lewis-Beck and Paldam (2000), and Stegmaier and Lewis-Beck (2013). While these essays highlight studies in the democracies of North America and Europe, economic voting work in the democracies of the rest of the world proceeds apace. (On these regions, see the review of Lewis-Beck and Stegmaier, 2008.) One final, general observation is worth making, with respect to this growing body of research. In virtually every democracy that has been investigated, the economic vote has appeared, as a statistically significant, and usually substantively significant, force shaping electoral outcomes, helping ensure Democratic accountability of the leaders to the people.

Abstract

Economic geography is a branch of human geography that deals with all matters of economic interest, from livelihoods and resource extraction, to production and exchange, to consumption and disposal. The definition of what is economic includes what is within formal economies and paid labor as well as informal production and services and subsistence agriculture. These embrace all of capitalism as well as what is just beyond its boundaries. Fundamentally, economic geographies do not view the economy as distinct or independent from social, cultural, and political processes. A hallmark of economic geography is that it is ever-changing, applying, and incorporating new ideas from other disciplines to enrich our knowledge of things economic. The overriding concern of economic geographers is to understand the world as it actually exists, rather than as it might be modeled.

Economic geography is a branch of human geography that deals with all matters of economic interest, from livelihood to resource extraction, to production and exchange, to consumption and disposal. The field has grown markedly in breadth from the early twentieth century when the focus of what was called commercial geography was primarily restricted to resources, mining, manufacturing, commercial activity, and trade flows of commodities and products.

The scope of economic geography encompasses theoretical and empirical research on what are viewed as economic activities. Economic activity, in the form of livelihood strategies within and outside of capitalism, has always existed. Global capitalism has made money and the need for money more widespread and multinational firms have brought formal jobs to more (but not all) places. The definition of what is economic includes what is within formal economies and paid labor as well as informal production and services and subsistence agriculture. Thus, economic geography encompasses all of capitalism as well as what is just beyond its boundaries. A hallmark of economic geography is that it is ever-changing, picking up new ideas from other disciplines to enrich our knowledge of things economic. This openness to new ideas and to analysis of new and rapidly changing phenomena encourages diversity within the subfield.

The resulting variegation belies several broad commonalities among economic geographers, evident in a common belief that the spatialities of the economy are not exogenous but are constructed or produced, and that institutions, governance, regulation, social construction, and indeed politics must be included (Sheppard et al., 2012).

Background and History

Economic geographers were at the forefront of the quantitative revolution of the 1960s, focusing on location theory and data-rich quantitative analysis. Industrial geography was for a time a thriving subfield, enriching our knowledge of multinational corporations as they came to dominate the global economy. Economic geographers continue to focus on understanding the firm (Taylor and Oinas, 2006).

Until the late 1970s, it was relatively straightforward to define economic geography; the field encompassed industrial and commercial activities as well as resource extraction. Rural primary sector activities received minimal attention, except as they provided raw materials for industrial activities or food for urban markets. Globalized agribusiness illustrates the central role of large, transnational firms in the organization of economic activities. Global production networks (GPNs) largely shape the extraction of other resources as well.

Manufacturing and its locations were of interest, as they varied markedly from country to country, and remain a focus of industrial geography. The emergence of postindustrial occupations, particularly in information and knowledge-related sectors, led to a new focus on the service economy. Similarly, global trade has expanded as free trade doctrine has prevailed in economic policy, generally leaving aside questions of uneven development.

The decline of manufacturing in wealthy countries gave rise to the study of economic restructuring as large firms shifted production to lower wage locations. Not only cities but also rural areas are affected by restructuring, as farms add tourism and other activities to agricultural (food and fiber) production. Global commodity chains (GCCs) link areas where (food and nonfood) crops are grown to the demands of (typically) wealthy, urban consumer markets.

Services became the dominant employer in rich countries as manufacturing shifted to locations with lower wages. Through the spread of multinational (or transnational) enterprises, transportation and communication grew as subfields central to the global economy. The concept of spatial divisions of labor (Massey, 1995) has developed into sophisticated study of GPNs. GPNs incorporate many kinds of relationships and network configurations, and they expand beyond interfirm transactions to encompass all relevant sets of actors and relationships (Coe et al., 2008).

Among services, finance is special, the lubricant of the global capitalist economy. The geography of finance has risen in significance as the intertwining of financial institutions, corporations, and consumers (Clark and Wójcik, 2007). Since the global financial crisis of 2008, the fates of governments, firms, and individuals have become even more confusing in

the continuing unsettled nature of debt and finance in the euro zone and beyond (Lee et al., 2009).

Retailing, which supports the business of consumption, has not been neglected. The sector ranges from locally owned shops to massive global firms with thousands of stores. The global retail giants, such as Wal-Mart and Carrefour, and hundreds of small chains, make decisions that determine the nature and locations of the many sites of economic activity, from the manufacture of goods and warehouses to the sites of retail shops and malls (Wrigley et al., 2005). Online e-commerce has added a new, virtual dimension to consumption.

Some subfields of geography began within economic geography but now thrive largely in lively specialized and interdisciplinary subfields, including entrepreneurship, transportation, and tourism. Much of economic geography takes place within cities and urban areas; urban geography is a vibrant subfield that encompasses the variety of human life and its manifestations that are found in cities. Effects of economic processes on places give rise to uneven development and inequality at many scales, from local and regional to national and global.

Aoyama et al. (2011) provide a concise list of the key agents in economic geography: labor, firms, and states, and key drivers of economic change: innovation, entrepreneurship, and accessibility. Economic change as it takes shape in industries and regions includes industrial location, industrial clusters, regional disparity, and post-Fordism. Global economic geographies address core-periphery, globalization, and circuits of capital. In all of these, economic geographers seek to understand the world as it actually exists, rather than as it might be modeled.

Theory and Methods

Recent and ongoing transformations of capitalism have prompted attempts by economic geographers to understand its workings in organizations such as firms as well as its effects on the ground, particularly in cities. A prominent example, going on for decades, is the shift from manufacturing and its demand for physical labor toward services and knowledge work. The new forms of capitalism call for theory that involves people as more than merely labor, encompassing capabilities and emotions. These changes in labor and life have profound impacts on cities and theories to explain them, not least in a new division of labor between a cognitive–cultural class and a service class (Scott, 2011).

The breadth of economic geography is striking, marked by interdisciplinarity. Since the 'cultural turn' in the 1990s, there has been a growing use of the term 'economic geographies' in which the economic and the social are seen as inseparable. Rather than assuming one economy and a market that sets prices, wages, and other dimensions of value, economic activity, economic life, and therefore economic geographies are complex, practiced, and entangled in particular places and times (Lee, 2006).

Corresponding to its breadth, the methods of economic geography have evolved from mainly looking for patterns based on large data sets to include qualitative research on relatively small numbers of subjects in an effort to uncover the complexity of actual economic geographies in particular places. Both types of research are common, as are frequent syntheses from neighboring disciplines that offer new insights to the issues within economic geography(ies).

Economic Geography and Geographical Economics

From the late 1950s through the mid-1970s, economic geography was aligned with economics in the interdisciplinary field of regional science through a common reliance on mathematical models in location theory, for example, and quantitative empirical analysis of industries and labor. The deindustrialization of Western economies beginning in the late 1960s precipitated a divergence between geography and economics. Geographers began a serious effort to understand capitalism and the social construction of the diversity of things economic. There remains a research effort in quantitative economic geography, often called regional political economy (Sheppard, 2011).

Economists have held true to their disciplinary core and its central models, whereas geographers have searched for explanations and solutions in other disciplines. The result, still ongoing decades later, has been an explosion of research by economic geographers to understand structural shifts from manufacturing to services, information, innovation, and knowledge; cultural shifts that recognize the diverse actors in economic activity; and technological shifts that facilitate customized and personalized products and a global reach through information and communication technologies (ICTs) such as the Internet.

The rise of the 'new economic geography' (NEG) also laid to rest the mutual respect between economists and geographers that had prevailed to a large degree within regional science. Paul Krugman's model of economic geography quickly became the standard (Krugman, 1991). In 2008, Krugman's receipt of the Nobel Memorial Prize in Economic Sciences for his contributions to new trade theory and NEG conferred further legitimacy on what has become known as the NEG. This model provides a central core for geographical economists. For economists, the benefits of a tractable model with restrictive assumptions and a set of 'modeling tricks' are preferable to the complexities of the real world (Krugman, 1998). The simplifying assumptions, however, strip away social, institutional, cultural, and historical context, and geography is reduced to transport costs.

Reactions to NEG have highlighted afresh the contrasts between economists and geographers in fundamental beliefs and methods. In particular, economists gravitate toward mathematical models and a focus on equilibrium (or, at most, multiple equilibria), whereas geographers tend toward in-depth case studies, real-world examples, and qualitative methods as they study an economy in constant change (Martin, 2011). Economic geographers, in contrast to economists working within NEG, have continued a spatially aware synthesis of ideas drawn from many disciplines. Indeed, the breadth and diversity of economic geography have become hallmarks of the field (Duranton and Rodriguez-Pose, 2005).

A central cause of the distinct stances of the two disciplines is the neat assumed world of economic theory and the messy

and diverse nature of 'the economy.' Whereas the mainstream economic view is of transactions of wage labor and private property in markets with ample finance, Gibson-Graham (2006) proposes a diverse economy depicted by an iceberg. Like an iceberg, only the visible tip on the top is the traditional capitalist economy and the larger part, beneath the water line, is a variety of ways in which people make their livelihoods and seek to survive outside the formal economy.

Within the formal economy, gender shatters the notion of 'economic man' and homogenous actors. Since the 1980s, feminist researchers have added new richness to economic geography. Significantly, feminist economic geography highlights the difference that gender makes, and the work and lives of women within as well as outside the formal labor market (McDowell, 2009). Gender-specific social stereotyping of occupations and domestic roles create very different geographies (Massey, 1995; Johnson, 2011).

Fundamentally, geographers prefer to see the world as complex and continually being made, with the economic inseparable from the cultural and social. Geography's inherent interdisciplinarity is seen vividly in the degree to which economic geographers read and utilize research by scholars in other disciplines (Duranton and Rodriguez-Pose, 2005). Overt attempts at dialogue can be seen in the *Journal of Economic Geography*, edited by economists and geographers. In most other respects, the two disciplines interact or converse very little.

Although economic geography's relationship with economics is tense, at best, economic geographers remain engaged with various branches of heterodox economics. Here, outside mainstream economics, mathematical models are not mandatory, and appreciative or verbal theory accounts for more of the complexities of the real world. In innovation studies, geographers contribute on an equal footing with researchers from business, management, and organization studies. This interdisciplinary area has seen bursts of research on such topics as industrial clusters, technological learning, and territorial knowledge dynamics.

Objects of Study

Economic geographers have studied a diverse range of phenomena and processes: learning and innovation; industrial organization; market systems; networks and globalization; livelihood strategies; development; race, class, and gender relations; neoliberal governance; and consumption. What links these often distinct foci and their literature is an explicit interest in what Jones and Murphy (2011) call "socioeconomic practices." These are the stabilized, routinized, or improvised social actions that constitute and reproduce economic space, through and within which diverse actors (such as entrepreneurs, workers, caregivers, consumers, and firms) and communities (industries, places, markets, cultural groups) organize materials, produce, consume, and/or derive meaning from the economic world. Practices may not only serve instrumental purposes (such as production, consumption, and learning), but they are also significant analytically because they can reveal the complexities, contingencies, identities, and meanings inherent in the many forms of economic organization (Jones and Murphy, 2011).

Relational economic geography "seeks to identify the complex relational geometry comprising local and non-local actors, tangible and intangible assets, formal and informal institutional structures, and their interactive power relations" (Yeung, 2005: p. 48). The focus is on actors and their actions and practices within the "multitude of material, labor market, technology, and information linkages" which comprise any commodity chain or production structure (Bathelt and Glückler, 2011: p. 8). Networks of all sizes and shapes serve to illustrate the relational economic geographies of real people in real places and economic activities. Power relations permeate the governance and regulation of all such relationships, producing new inequalities and reinforcing old ones.

Cultural economic geography embraces all ways in which the cultural and the social shape the actions of economic actors and the economy itself. This perspective acquired greater importance as more and more 'noneconomic' features were recognized as being intertwined with economic activity (James et al., 2007). Moreover, culture and creativity also are produced, distributed, exhibited, and consumed as cultural products, services, and experiences.

Thus, geographies of production focus on economic systems as networked formations, constituted by a mesh of relationships that operate within and across the global, national, and regional/local scales. At the global scale, the idea of GPNs (or GCCs or global value chains) has helped to uncover the webs created by transnational firms and the many affiliates, partners, suppliers, and subcontractors that underlie the more-or-less visible global capitalist economy (Coe et al., 2008).

Evolutionary economic geography (EEG) draws on parallel work in evolutionary economics, an established heterodox branch of economics, and also combines formal modeling typical of neoclassical economics with the contextuality of human decision-making, such as local history and institutions. In general, EEG attempts to explain regional growth differences from the microhistories of firms that operate in territorial contexts.

The goal of EEG is to interpret and explain how the economic landscape changes over time, and to demonstrate how geography matters in determining the nature and trajectory of evolution of the economic system (Boschma and Martin, 2010). Among the principal challenges is to understand the spatialities of novelty (innovations, new firms, new industries, new networks) to explain path creation and emergence rather than only path dependence. The evolutionary research effort is wide-ranging, incorporating Darwinian concepts from evolutionary biology, complexity theory such as emergence, and mechanisms that lead into – and out of – path dependence. MacKinnon et al. (2009), however, suggest that a stronger basis in institutional economics and political economy is needed to relate the evolution of the economic landscape to processes of capital accumulation and uneven development.

All of the perspectives above, each with its own preferred methodologies, struggle for attention and dominance of theoretical and empirical study. All perspectives aim to

comprehend the economic geographies that evolve and manifest simultaneously but differently at global, national, and regional/local scales. The degree to which any actor and its networks are embedded in any specific context is among the concerns for theory and empirical research alike.

On the whole, economic geography is characterized – and contrasts sharply with economics – by having no canon of standard models and tenets; being intellectually diverse and porous, welcoming and receptive to new ideas; and therefore having inherent interdisciplinarity. Fundamentally, economic geographies are socially constructed and sustained, enmeshed in social, cultural, and political processes.

Empirical Challenges: The Economic Geographies of a Changing World

The overriding concern of economic geographers is to understand the world as it actually exists, rather than as it is stripped of complexity so that it can be modeled mathematically. The spread of multinational firms provides employment and income for some, while livelihood strategies within and outside of capitalism are still common. New sites of growth, particularly East Asia beginning with the rise of the Japanese economy in the 1970s and of Chinese economy in the 1990s, have added to our knowledge of non-Western varieties of capitalism.

Virtual or Digital Economies

The virtual economy or digital economy, facilitated by ICTs, is another venue within which economic activity takes place. The virtual economy adds new meanings and measures to the concepts of distance and proximity. Digital technologies enable more activity in more places, work tasks can be done 'offshore,' and new firms can be 'born global.' At the same time, many long-standing inequalities remain as new technologies favor established wealthier markets. Mobile phones and digital technologies are changing the lives of small farmers in the global south by reducing the barrier of distance and altering access to information about markets and prices.

Environmental Economic Geographies

The environmental impact of economic activity has emerged into environmental economic geography. Environmental economic geography works to understand environmental impacts as largely an outcome of the decisions and business practices of firms, whose pursuit of profit has seldom taken the environment into account. The general outlines of environmental economic geography acknowledge that substantial changes in technologies, industries, and lifestyles – and in technoeconomic paradigm – are needed to create a 'sustainability transition.' The global study of waste by Crang et al. (2013), who have followed goods past consumption to recycling, has uncovered significant activity in informal networks, again illustrating a large iceberg of informal activity beneath the surface of the formal economy.

Asia in the Global Economy

The shift in economic power to Asia began in the 1970s as Japanese firms outcompeted companies from Europe and North America in products such as cars and electronics. Other Asian firms, first from the 'four tigers' (Hong Kong, Singapore, South Korea, and Taiwan) soon followed. Each economy had a combination of government policy and learning from the best practices and mistakes of others. The result has been an evolution from followers to market leaders, notably in the electronics industry (Yeung, 2009).

The opening of China's economy to global capitalism – albeit with Chinese characteristics and control – has led to new 'divergent hybrid capitalisms in China' (Yang, 2007). In various ways, Chinese firms (from mainland China, rather than from Taiwan or Hong Kong), enmeshed with the Chinese state, have become major actors in the global economy.

Latin America, Africa, and the Global South

In the midst of Asia's growing 'clout' in the global economy, other regions have been relatively neglected within economic geography. In Latin America, economic geography remains focused on the postcolonial effort against neoliberalism (Werner, 2012). African economies likewise are changing. The 'new scramble for Africa' is the effort by large firms – now including those from China as well as from the West – to secure supplies of oil and other minerals as well as food supplies (Carmody, 2009). At the same time, another new scramble – for livelihoods – continues and drives rural change and urbanization (Bryceson, 2002). The results of sudden change include immense economic and social disparities within African cities.

The search to understand the world of practices and work outside capitalism leads economic geographers to examine inequalities at a global scale, in the world economy's 'periphery,' and in the Global South. Typically the focus of development studies, several phenomena, including globalization, industrial location, migration, and poverty, have become critical issues in rich and poor countries alike. Development research, long the global view of economic geographers, faces new challenges as the global economy becomes ever more non-Western.

Conclusion

Economic geography has blossomed well beyond its original focus on the location of production to embrace the many other human forces – social, cultural, political, and institutional – which affect and are affected by economic activity. Constant change ensures that new ideas and new empirical knowledge are always characteristic of the field, and this attracts new researchers and their fresh thinking and new approaches.

A group of midcareer (i.e., not senior) geographers recently have proposed a research agenda for economic geography, centering on five research themes on which too little is known: networks, firms, and markets; economic geography of global

environmental change; the geography of finance; digital property including challenges, processes, regulation; and a more 'global' economic geography (Benner et al., 2011). These and other emerging topics will be among the future economic geographies to be written.

Economic Growth

David de la Croix, IRES, Université catholique de Louvain, Louvain-la-Neuve, Belgium

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The first challenge for economic growth theory is to understand the transition from stagnation to growth at the time of the industrial revolution and in particular to identify the main factor(s) that triggered the takeoff. Doing so also helps to understand why there are poor and rich countries today, and whether the poorest ones will ultimately catch up. This article reviews the main theories of growth, including the Malthus model (useful to understand stagnation), the neoclassical model where technical progress is the engine of growth, the endogenous growth model where growth is self-sustained and policy is of particular importance for the long run, and unified growth theory, providing the big picture and linking the growth takeoff to the demographic transition.

Definition and Measurement

Economic growth is the process by which the amount of goods and services one can earn with the same amount of work increases over time. It generally implies that income per person rises over time (unless hours of work fall steadily).

Almost everything people buy today requires fewer days of work than it did in the past. A classic example is provided by Nordhaus (1996: Table 1.6) in his history of lighting. According to him, 10 min of work today buys 3 h of reading light each night of the year, while it only bought 10 min of light per year two centuries ago.

Growth theory attempts to model and understand the factors behind this process. It is a relatively young field of research, as one can establish by searching for 'economic growth' in all the books published, which have been scanned by Google (about 10% of all books). **Figure 1** shows that the emergence of the field can be dated to the 1950s.

For a relevant theory of growth, one needs good data first. Measuring growth is difficult, especially for periods for which little information is available. National Accounts were set up in most countries after World War II. They provide different ways to measure income per capita (Gross Domestic Product (GDP), etc.). Making data comparable across countries requires correcting for differences in price levels to obtain estimates that capture the real purchasing power of income. The most comprehensive database so far is the Penn World Tables version 8.0 (Feenstra et al., 2013), which provides information on relative levels of income, output, inputs, and productivity, covering 167 countries between 1950 and 2011. Going back in time was the task undertaken by Maddison (2001). Based on a broad set of historical studies, he reconstructed income per capita data over the past two centuries, and added some point estimates for earlier periods (in CE 1, CE 1000, CE 1500, CE 1600, and CE 1700). Such estimates very often require educated guesses on unobservable trends, but they have the great merit of showing the best, which can be done given what is known at one point in time. Very recently, Maddison's successors have been revising and completing his work (the 'Maddison project,' Bolt and van Zanden, 2013). **Figure 2** presents the latest estimates for GDP per capita.

Figure 2 shows that, over the past millennium, income per capita in our selected countries has increased 32-fold, from \$717 per person per year around the year 1000 to \$23 086 nowadays. This contrasts sharply with the previous millennia, when there was almost no advance in income per capita. The figure shows that it started rising and accelerating around the

year 1820 and it has sustained a steady rate of increase over the last two centuries. One of the main challenges for growth theory is to understand this transition from stagnation to growth and in particular to identify the main factor(s) that triggered the takeoff.

Before looking into possible explanations, it is worth wondering how robust the finding that there was stagnation in the standard of living until 1820 is. This claim is particularly striking given that mankind experienced significant technological improvements that can be expected to increase productivity and income per person, from the Neolithic revolution to the invention of the printing press. Three facts corroborate the idea that there was indeed stagnation over the most part of human history: first, estimates of life expectancy computed on specific groups across time and space do not display any trend before CE 1700 (de la Croix and Licandro, 2013). Second, body height computed from skeletal remains does not display any trend either, while height is known to depend very much on nutrition when young (Koepke and Baten, 2005). This indicates that there was no systematic improvement in nutrition over time. Third, real wages computed from historical sources did not tend to rise in any sustained way before the industrial revolution (Allen, 2001).

Theories of Stagnation

How can it be that technical progress did not lead to a better standard of living before the last few centuries? The answer can be provided by mobilizing the so-called 'Malthusian theory,' attributed to Malthus (1798), inspired by previous work such as the chapter on the obstacles which oppose the excess of population in the human species by Bruckner (1767). This theory was formalized recently by Ashraf and Galor (2011). The theory has two basic ingredients. The first one is the production technology. It assumes that farms produce output from land and labor, where land is a fixed factor, and labor displays diminishing marginal returns. Diminishing returns imply that adding more labor while holding land constant yields lower productivity per person. The second ingredient is the assumption that fertility net of mortality is an increasing function of food per person. Less food per person yields higher mortality ('positive checks' in Malthus' terminology) and lower fertility (people marry later and have fewer children, 'preventive check' for Malthus). When there is an increase in technology, for example, when metal tools were invented, the generation at the time of the invention is better-off. When there is more food per person, fertility increases. The next generation is more populous, which lowers each worker's productivity because of diminishing marginal returns (the fields are crowded with laborers). As time passes, the population converges to a new steady state, and the food per person goes back to its initial level: the increase in productivity made possible by the discovery of metal tools is exactly offset by the decrease in productivity generated by the rise in population. In sum, technological improvements lead to a larger population, but not to a higher standard of living.

Before describing how economies can escape this logic, let us contrast the Malthusian model with the theories accounting for growth in the recent period.

Theories of Growth: Neoclassical Growth

The rise in per capita income did not happen everywhere in the world. The gap between the leading regions and the poor ones has actually increased over time. Citizens from Western Europe were three times richer than African citizens around the year 1820: now they are 13 times richer. To understand why countries differ so dramatically in terms of standard of living, the factors behind the success or the failure of the growth process in different parts of the world must be identified.

The first possible factor in the growth process is the accumulation of physical capital. For capital to drive growth steadily, the output of an economy needs to be proportional to the stock of capital used in production. In this case, growth will be proportional to investment. This accumulation through investment may come about either through local saving or investment from abroad. A theoretical argument against this view claims that marginal returns to capital are decreasing, i.e., one cannot increase production per worker indefinitely simply by increasing the stock of capital per worker. If machines per employed person grow at a constant rate, the growth of output will eventually drop to zero. Workers, whose number is bounded by the active population, cannot deal with many machines with the same efficiency as they cope with fewer machines.

While decreasing marginal returns on capital may make it impossible to sustain growth by investment alone, it remains true that capital is one of the most important determinants of growth in the medium run. McGrattan (1998) finds a strong positive relationship between average rates of investment and growth in postwar data for a large cross-section of countries. The typical example of such a relationship is the emergence of the East Asian tigers, which managed to catch up with rich countries in the second half of the twentieth century essentially by accumulating capital. However, Zambia's experience provides a counterexample. If all the aid to that country had been invested, and if investment had gone into growth, Zambia's income per capita would actually be $20 000 instead of $600 (Easterly, 2001).

Since physical capital cannot be the engine of growth when marginal returns are decreasing, another variable must account for rising per capita income over time. Neoclassical growth theory, pioneered by Solow (1956), assumes that technological change is exogenous to the economic system. In his model, technological change is the main source of growth by making labor more efficient, i.e., better able to work with many machines. Such technological change is labeled 'labor-saving technical progress.' In Solow's model, population growth is exogenous and does not respond to an increase in standard of living. In addition, there is no fixed factor, such as land, in the production process. These two features explain why technological progress drives growth in the Solow model, but not in the Malthus model.

Neoclassical growth, with its decreasing return to capital and exogenous technical progress, has strong empirical implications. First, it implies that there should be a convergence in income per capita across countries, i.e., countries that are further away from their long-run balanced growth path should grow faster than countries, which have already accumulated most of their capital. This is because the benefits

Figure 3 GDP per capita in Haiti and Dominican Republic. Logarithmic scale. Horizontal line = 5000 dollars (1990 GK$). GDP, Gross Domestic Product.

from increasing capital (i.e., the marginal productivity of capital) are higher in countries with little capital, and lower in countries with a lot of capital. According to this theory, investment should flow from rich countries to poor countries in search for better returns, and the income gap between countries should shrink over time. There is a vast empirical literature studying the existence and the speed of such cross-country convergence (see Durlauf and Quah, 1999). At the end of the 1990s, the consensus was that there is some convergence in the data, but at a much slower pace than predicted by the theory. Moreover, some groups of countries seem to be trapped on a low-growth path. This conclusion is now partly reversed, with the fast growth experience of East Asia, and inequalities across countries are clearly on the decline (van Zanden et al., 2014).

A second implication of neoclassical growth is that policy affects the level of income per capita, but has no grasp on its long-run growth rate. Bad governance cannot affect the growth rate of the economy, as the latter is determined by the growth rate of exogenous technology. Comparing the growth experience of countries with similarities (suspected of having the same growth rate of exogenous technology), this prediction of the theory seems at odds with the data – as exemplified by the experience of Haiti and the Dominican Republic. The two countries share the same island, had the same GDP per capita in 1950 (1027 dollars per person for the Dominican Republic and 1051 for Haiti), but their growth trajectory diverged, as shown in **Figure 3**. This divergence is likely to be attributed to better governance in the Dominican Republic. If this divergence of the two countries is considered as a long-run phenomenon, one should conclude that policy really matters for the long-run growth rate, which calls for developing another theoretical framework. This is what endogenous growth models are about.

Theories of Growth: Endogenous Growth

Modeling growth itself as an endogenous phenomenon requires getting rid of the decreasing returns to factors of production that the economy can accumulate (physical or human capital). Externalities (spillovers) play a central role here. If, when a firm or an individual invests, this investment has positive spillovers on other firms or individuals, the private return of the investment (to the firm or the individual) is smaller than the social return (to all firms or individuals together). Investments may thus still have decreasing private returns, but constant social returns thanks to spillovers. For example, investments in research leading to advances in knowledge benefit the firm, which has invested in them, but with decreasing returns (otherwise the firm would tend to invest infinitely). Such advances, however, benefit the whole society at a higher, and nondecreasing, rate.

Accordingly, endogenous growth can be based on the fact that advances in knowledge, e.g., in basic science, have led to technological progress. Growth theorists have pointed to the importance of what they have termed a research and development sector, which either invents new goods or increases the quality of existing goods (see Barro and Sala-I-Martin, 1995). This theory attributes a preeminent role to the R&D sector in generating growth, and makes a crucial link between innovation and market power. Indeed, the incentive to innovate is provided by monopoly rights on the new goods, which grant extra profits to research firms. Such models also open up interesting policy debates, essentially on the optimal patent protection laws, and the optimal level of subsidies required to stimulate research.

Accumulating human capital is the other way to sustain a growth process. Indeed, even if a country cannot increase its supply of labor indefinitely, it can enhance the quality of labor. This quality is referred to as 'human capital,' and incorporates education, experience, and health. Human capital can be accumulated in two ways: during the early stage of life by going to school and spending on education; during the working life by accumulating experience (learning-by-doing) or by on-the-job training. Investment in formal education has increased substantially all over the world. In England, for example, the number of years spent at school went from two on average in 1820 to more than 14 today. In developing countries, school enrollment grew rapidly between 1960 and 2000. Although many poor countries experienced an educational boom, they did not start growing more quickly. In general, empirical studies stress the lack of correlation between educational attainment and growth performance. The accumulation of human capital is a necessary condition for growth, but it does not seem to be a sufficient condition.

Institutions are often blamed or praised for their role in promoting growth. In endogenous growth models, good or bad policy may indeed permanently affect the growth rate of the economy itself. Acemoglu et al. (2002) argue that relatively rich countries colonized by European powers in the 1500s are now relatively poor and vice versa. They explain this 'reversal of fortune' by the types of institutions imposed by European settlers. 'Extractive' institutions were introduced in the relatively rich countries for the benefit of the settlers rather than to increase general prosperity. In the relatively poor areas, there were fewer incentives to plunder, and so to prevent the development of investment-friendly institutions. As a result, the decline or rise of those countries is rooted in a major – exogenous – institutional change linked to colonization. A number of authors have also linked the poor performance of

many developing countries with governance issues: corruption, ethnic fragmentation, wars, etc.

Theories of Growth: Poverty Traps

An alternative explanation to the lack of convergence across countries relies on poverty trap models. They are based on the idea that the marginal return of capital is not systematically decreasing: for some range of values of capital, there can be increasing marginal returns. For example, suppose that two technologies of production exist, the traditional one and the modern one. Switching to the modern technology allows for a discrete jump in the productivity of factors of production, but requires accumulating a certain level of capital per worker. If an economy has a capital stock close to this level, a small increase in capital will lead to a large jump in productivity, hence displaying increasing returns around the critical level of capital. A similar reasoning can be applied to human capital as well. Such a framework leads to predictions that differ drastically from the neoclassical growth model. Instead of a convergence of all countries to a similar long-run balanced growth path, now the long-run outcome depends on the initial conditions. An initially poor country with a low level of capital per worker might be 'trapped' in a low equilibrium, while an initially richer country may grow toward the high-balanced growth path. For the same reason, countries that are very similar initially may have a diverging growth experience, if they start on each side of a critical threshold. With poverty trap models, Figure 3 can be interpreted as reflecting that Haiti had slightly worse initial conditions, and this led to a drastically different development. Here, it is not governance, which is to be blamed, but bad luck.

Endogenous growth models and poverty trap models also differ drastically in their policy prescriptions. While endogenous growth leads to advise countries to improve governance and productivity, poverty trap models require some aid to be given to the country, to help it bypass the critical level of accumulation it needs to grow in a sustained way.

Poverty trap models essentially capture vicious cycles. In the example above, low development prevents the country from adopting modern technology, which perpetuates low development. Other mechanisms can be invoked: because government employees are underpaid, they ask for bribes, which discourages investment, keeping the country in poverty. Alternatively, a low level of human capital implies bad teachers, which perpetuates broken education systems and low human capital.

Poverty trap models are not only able to account for successful and unsuccessful growth experiences, but they can also explain why some economies have experienced relative, or sometimes absolute, periods of decline. Kindleberger (1996) defends the view that economies, like human bodies, go through a life cycle, in the course of which 'vitality' varies, depending on how entrepreneurial each generation is. The Venetian Maritime Republic declined when leaders started devoting more time to consumption rather than to investing in the improvement of shipping techniques, the discovery of new maritime routes, etc. Florence and its famous banking sector declined when Lorenzo the Magnificent delegated power over the Medici bank branches as he was spending more time on luxury and pleasure. In order to capture the idea that rich regions tend to rest on their laurels, and are inclined to favor consumption over investment in knowledge, habit consumption models can be used (see Artige et al., 2004). This approach suggests that the desire to consume depends positively on past consumption (either of the individual, or of his or her parents, or of society as a whole). Eventually, the new generation in the richer regions develops living standards that are incompatible with the continuing investment in knowledge that is required to maintain economic leadership. This reduces the growth rate in comparison with other regions. At some point in this process of decline, consumption falls to a low level once again, and a new growth cycle may start.

The Transition to Modern Growth

The models of neoclassical and endogenous growth describe very aptly what happened in the last two centuries, but they are totally unable to explain the stagnation period. The Malthusian model, on the contrary, gives a very nice description of stagnation, but cannot account for growth takeoffs. Finding a single framework, which can explain the whole path of income over history has been the task of growth researchers in that last 15 years. Explanations can be divided into two broad classes. The first class relies on exogenous causes; the second one builds a setup in which everything is endogenous.

Before turning to the different types of setups that have emerged to explain the full pattern from stagnation to growth, it is necessary to stress that the growth takeoff was systematically accompanied by a demographic transition. Figure 4 shows the demographic transition in Sweden, together with the growth takeoff. Birth and death rates were systematically high before the takeoff, then mortality went down, while fertility stayed high for some time. During this period, population size increased fast. Then fertility dropped quickly and population growth decelerated. Once the transition was

Figure 4 Left axis: crude birth rate (dark gray dashes) and crude death rate (light gray dots) in Sweden in per 1000. Right axis: GDP per capita. Logarithmic scale (1990 GK$). GDP, Gross Domestic Product; CBR, crude birth rate; CDR, crude death rate.

achieved, both birth rate and death rate were low, and population growth became negligible (or even negative in some cases). The demographic transition took two centuries in England and other European countries. In East Asia, it was much faster, of the order of half a century. Causality between the two transitions goes both ways: the demographic transition was triggered by the income takeoff, at least as far as the drop in mortality is concerned, while the takeoff was made possible by the demographic transition, because allowed to invest in the education and health of a smaller number of children.

Exogenous Models of the Transition

To return to the inability of the stagnation model and/or the neoclassical growth model to account for the whole historical path of income, Hansen and Prescott (2002) show that the two approaches can be combined in a single framework, which models the takeoff. The idea is as follows. There are two sectors of production, agriculture, and industry. Initially, the technological level and productivity in the industry are very low, so that the resources of the economy, including labor and capital, are all employed in the agricultural sector. As this sector is subject to decreasing returns to labor and to the constraint on available land, the model behaves as the Malthusian model. Then, with exogenous technological improvements, the industry sector becomes profitable and starts attracting resources. As time passes, resources move from agriculture to industry. The economy becomes more and more similar to the one described in Solow's neoclassical growth model.

In this theory, the process forcing the transition is exogenous. If interpreted literally, it consists of improvements in the productivity of the industry. In a broader sense, it can also reflect (exogenous) improvements in institutions. The Enlightenment can be seen as one of those changes, which made knowledge more useful for growth (see Mokyr, 2012), through the primacy they gave to reason over superstition and tyranny. The Enlightenment itself was rooted in the Protestant Reformation, which opened the path to questioning received authority, and hence, to critical scientific thinking.

Other types of exogenous explanations for the takeoff rely on incentives to accumulate human capital. If, for some reason, it becomes profitable for households to invest in education, growth can be sustained thanks to the human capital externalities stressed in the endogenous growth model literature. Two types of shocks are considered here. The first is based on Ben-Porath (1967)'s idea that the return to investment in education depends on the length of time during which education will be productive, implying that a longer active life makes the initial investment in human capital more profitable. Provided that human capital is an engine of growth, an initial increase in longevity (for exogenous biological/climatic/medical reasons) may, in turn, sustain the permanent accumulation of human capital and income growth (see, e.g., Cervellati and Sunde, 2005). The second type of shock triggering education can be institutional. For example, Engerman and Sokoloff (2002) identify conditions under which a country will introduce public education early, favoring a skilled workforce and a rapid industrial revolution.

Finally, the quest for deeply exogenous mechanisms to explain growth and development has led several authors to look at the prehistorical determinants of modern growth patterns. The most well-known approach is the one put forward by Diamond (1999) for whom Europe and Asia benefitted from two geographical advantages compared to other continents: the natural availability of domesticable plants and animals (among the ancestors of the 14 big domestic animals, 13 come from Eurasia and North Africa, with the 4 most important ones coming from the Fertile Crescent), and the East–West orientation of the continent, which favored the spread of knowledge and diseases (hence allowing immunization).

Unified Growth Theory

Unified growth theory, a term coined by Galor (2011) and his coauthors, shares the same ambition to explain income history in a single setup. Contrary to the previous approach, it does not rely on exogenous changes in technology or institutions, but embeds the mechanisms of change into the model itself. In the early stage, the economy is characterized by a stable Malthusian equilibrium. Population increases slowly as a consequence of technological progress. The slow increase in population density accelerates the pace of technological progress, as a denser population generates more ideas, allows for more specialization, and sustains bigger cities. Faster technical progress itself requires education to be implemented, and this rise in education leads the economy to accumulate human capital. As in endogenous growth models, this allows for sustained economic growth.

In the model above, population size plays a key role. During the stagnation period, all variables (income per person, etc.) are constant except for population size. At some point in time, it reaches a threshold above which the transition starts. Instead of basing the takeoff in income on the latent increase in population density, one can model the industrial revolution as resulting from a change in the composition of the population. Suppose that there are two types of people, and that one of the types, when present in large numbers in the population, generates the takeoff in income. If, during the stagnation period, this type benefits from an evolutionary advantage (which means it reproduces faster), then its share in the population rises slowly over time, and the takeoff ultimately occurs. This 'growth enhancing type' can be one, which values the education of children (Galor, 2011), or one with an entrepreneurial spirit (Clark, 2007). The question of the transmission of the type from parents to children, either genetically, or culturally, remains open. For this mechanism to work, a strong persistence of type across generations is indeed required.

The Quality–Quantity Trade-Off

Galor (2011) and many other authors have stressed that the link between the demographic transition and the economic

Figure 5 The quantity–quality trade-off for 1760–1965 birth cohorts in Sweden. Three measures of quality (body height, years of schooling, life expectancy at age 10), versus total fertility rate. All data normalized.

growth takeoff goes through the 'quality–quantity trade-off.' This originates in a simple budget constraint, which holds both at the individual level and at the country level:

$$\text{Total spending on children} = \text{number of children} \times \text{spending per child.}$$

Keeping the total spending constant, enhancing the 'quality' of children by spending more on each child requires reducing their number. Consequently, the drop in fertility observed during the demographic transition allows to increase education and health spending, thereby making the accumulation of human capital from one generation to the next easier. Figure 5 shows for Sweden that the drop in fertility comes with a sharp increase in formal education, with a rise in adult longevity, and with a rise in people's height, which signals better nutrition and a lower exposition to disease when young (see de la Croix and Licandro, 2013). Both education and health are key components of human capital.

Demographics also matter for growth through the 'demographic dividend' (see Lee and Mason, 2006). The view promoted by neoclassical growth was that a high rate of population growth could not be supported by a corresponding increase in investment, thus lowering growth of income per capita. This negative relationship between population and economic growth calls for population control policies. More recent empirical literature finds that in general there is a nonsignificant correlation in cross-country studies. From these studies, it is also clear that the impact of population growth has changed over time and varies with the level of development. The composition of the population, as well as age-specific variables, is relevant to growth. A decrease in the death rate of workers in particular does not have the same effect as a decrease in the death rate of dependents, young or old (Lindh and Malmberg, 2007).

Growth and Inequality

Finally, the relationship between growth and inequality has drawn attention. The question is twofold. First, does inequality evolve along with economic growth? The 'Kuznet curve' suggests that inequality first increases and then decreases in the course of the growth process. Second, is inequality good or bad for growth? Most of the existing literature on inequality and growth concentrates on the channels by which inequality affects growth, through the accumulation of physical capital. For example, in countries with many poor people, there is a high demand for redistribution policies, which in turn lead to tax distortions that slow down growth. Inequality can also influence growth because of its effects on the accumulation of human capital, in particular if the poor are subject to credit constraints, preventing them from investing enough in education. Finally, demographic variables must be taken into account in assessing the effects that economic growth may have on income distribution (differential fertility and mortality).

Abstract

Measuring economic performance of a country is – arguably – one of the most important contributions of empirical economics. Historically, the national income accounting system was designed for maximizing the government earnings by finding better ways of imposing higher taxes. In contemporary economies, economic growth and their estimation approaches have become instrumental in devising social welfare maximizing policies in a more systemic way. This article embodies most of the fundamental measuring techniques of national accounting system in retrospect, and indicates several secondary data sources that are widely used in growth empirics.

The history of economic growth measurement has been one of intimate interplay with economic theorizing, leading from improvements in the accuracy and relevance of growth data, to hypotheses on the critical sources of economic growth, to explaining deep changes in the structure of national economies. In the late sixteenth and seventeenth centuries, the national income accounting system was first introduced in England and France to support their sovereign regimes in maximizing the government earnings by finding better ways of imposing higher taxes. However their national accounting systems were very far from to provide reasonable estimates until the early twentieth century. In particular, when the great depression struck most of the rich economies in the late 1930s, the governments became objective in measuring the pulse of the economy in a more systemic way.

Economic growth is the sustained increase in welfare of an economy – nation, region, city – together with the ongoing changes in that economy's industrial structure; public health, literacy, and demography; and distribution of income. In the long run, as this economic transformation evolves, so do social, political, and cultural norms. Societies change profoundly and multidimensionally, as economic performance improves.

To measure economic growth is to quantify this increase in welfare and to endow with numerical precision these large-scale economic and social changes. Given the breadth of possibilities, it is impossible to undertake this measurement exercise without guidance – what can be pared away, what is essential – from some view on the causes of growth (*see* Economic Growth).

This article sets down some key (measurement) facts concerning economic growth, and documents how they have evolved, if at all, over time. In doing this, the article attempts also to illustrate the historical interplay between two lines of research – measurement of and theories about economic growth – each influencing the other.

National Income

The panorama above of profound social and economic changes can be simplified dramatically by concentrating on just a single key economic variable, national income. National income can be estimated mainly using three methods, of which all theoretically provide the same estimate: by summing up all *expenditures* within the country in a given year, by adding up all *income* earnings each year, or by adding up all the *value added* in a year. In sum, national income is the total value of all goods and services produced in an economy in a given year. The *economic growth rate* is the rate of change in national income from 1 year to the next. Income can similarly be estimated for more disaggregated geographic units, such as regions, states, and provinces.

Income per capita is income divided by population in the appropriate geographic unit, yielding a convenient first measure on the state of economic well-being. Since total income is the same as total output, this measure might sometimes be usefully replaced by output per worker, or labor productivity, where the denominator is then the size of the labor force; or, even output per worker-hour, where the measure then takes into account the time spent working by the labor force.

In some detailed analyses, these alternatives can provide different useful insights into economic performance – different countries, at different times, have had their labor force markedly different from their population, or have had workers and firms make different choices on the length of their workday. However, for the kind of long-horizon, large-scale developments that are typically of interest in economic growth, these differences are inessential. Potentially more important is whether this one measure can suitably proxy for the wide spectrum of different variables of concern in economic growth.

Across countries, per capita income is positively correlated with a broad range of alternative indicators for economic performance, as well as an array of health, educational, and institutional quality measures – including life expectancy (the negative of), infant mortality, adult literacy, rule of law, democracy, and so on. Thus, economists and many other social scientists have focused on quantifying the relationship between per capita income (both its level and growth rate) and indicators of living standards.

Historical Estimates

Economic growth – significant, sustained increases in welfare – is a relatively recent occurrence (Maddison, 1982; Romer, 1986). While steady improvements in the lot of humanity over the last 50 000 years had been noted, most of those came tortuously slowly.

In eighteenth century the Netherlands appeared as the leading economy in the world. However, economic growth there was neither sustained nor pronounced. Almost a century afterward, labor productivity in the Netherlands was 6% lower than that in 1700. In 1785 the UK had risen to the leadership of the New World economy. Despite immense strides in technological progress due to the Industrial Revolution, the UK's labor productivity grew, nevertheless, by only 0.5% per year from 1785 through 1820. From then to the beginning of the twentieth century, the UK remained the world's economic powerhouse. But in this time, too, the UK labor productivity grew relatively modestly, by 1.4% per year. Only after the US overtook the UK following the end of the nineteenth century, did the world begin to see the kind of long-run, sustained growth rates that are now typical: US labor productivity grew at 2.3% from 1890 through 1979.

In general, historical data on income before the nineteenth century were hardly available. In this context, Maddison (1995) estimated gross domestic product (GDP) for 56 countries for the period 1820 through 1992. Later, he proposed an estimate for world output in the year AD 1, which was approximately $105.4 billion at 1990 prices. Importantly, Maddison's estimates indicate that Asia produced more than half of world output for 18 of the last 20 centuries (*see* The Economist, 2010). His readings suggest that the growing convergence in the world economy is – therefore – a 'restoration' not a 'revolution.' Nonetheless, Maddison's national accounting has to be taken with caution. For instance, despite using Maddison's data in their research, Acemoglu et al. (2005) remained skeptical stating that Maddison's data set is *no more than educated guesses*. Recently, Bolt and van Zanden (2013) launched an updated version of the original Maddison data set revising the estimates of economic growth between AD 1 and 2010.

Kaldor's Stylized Facts

Not long after the concept of national income was developed, Kaldor (1961) observed that the ongoing growth in per capita national income came with several empirical regularities:

1. Income per capita grows steadily over long stretches of time.
2. Factor income shares – the fractions of total income accruing to the labor force and to physical capital – show no secular trend.
3. The ratio of total national income to the aggregate stock of physical capital – the total value of machines, highways, bridges, buildings, physical infrastructure – remains roughly constant.

These observations, typically labeled *Kaldor's stylized facts*, constitute a first important growth measurement that economists sought to understand and to explain.

According to Kaldor's measurements, while economic growth occurs, its benefits divide up in a stable way between rewards to capital and labor – no one factor input, taken as an aggregate, benefited more than another from economic growth. Moreover, since capital's income share can be viewed as the stock of capital multiplied by capital's rate of profit, Kaldor's stylized facts also implied that the profit rate is, in the long run, constant.

Physical Capital Accumulation

The most successful of the different explanations for Kaldor's growth observations was given in Solow (1956) and Swan (1956), who developed similar explanations simultaneously, but independently in different hemispheres of the world. This immensely influential work produced a widespread conventional wisdom, known as neoclassical growth theory, which had also a profoundly important policy implication. The line of work, however, then led to yet further measurements (Solow, 1957) whose later reinterpretation would eventually overturn the original consensus.

The neoclassical growth theory had investment – the accumulation of physical capital – constituting the critical engine of growth. It assumed that total output obeyed a *production function* taking values that increased with the quantities of physical capital and labor employed in the economy. Because no well-behaved function can give at all times a perfect fit relating output, capital, and labor, it was hypothesized further an unobservable residual to the production function relation, a residual that he interpreted as exogenously evolving *technical progress* or, more simply, technology. Together with some other reasonable assumptions on the behavior of savings (and therefore investment), labor force growth, and technology's impact on the effectiveness of labor and capital, the model generated outcomes successfully reproducing Kaldor's stylized facts.

The result envisioned had economic growth in two conceptually distinct phases. First, there is the long-run steady state, where the capital–output ratio is constant, and growth in per capita income occurs entirely from technical progress. Second, there is transition to the steady state: along this transition path, physical capital accumulates rapidly due to relatively high investment, driving up the economy's growth rate as the economy itself converges toward its long-run, steady-state growth path. If the second phase were that more relevant to the real world, as many supposed, then accumulating physical capital – building machines, factories, roads, and bridges – constituted the engine of economic growth. Policy-makers from Joseph Stalin in the Soviet Union through Lee Kuan Yew in Singapore through leaders in developing country after developing country took this implicit advice to form a cornerstone of their development plans. Encouraging savings – voluntary or forced – became key to economic progress.

In neoclassical growth theory, technology bore two different meanings. One, because by assumption it influenced the effectiveness of factor inputs, technology was also labeled *total factor productivity* (TFP) – it improved the productivity of all the factor inputs in an economy. Two, because it emerged as a residual in the production function accounting exercise, it was

also viewed, derisively, as a 'measure of our ignorance' (on the part of the modeler). Early research on growth measurement, therefore, took one of its goals to be the minimization of this residual, the idea being that the smaller TFP became, the more successfully one had explained economic growth.

Measurements undertaken by Solow (1957) showed that for the US over the first half of the twentieth century, almost 90% of economic growth was due to TFP, with only the remaining one-tenth accounted for by capital accumulation. Taken at face value, this surprising empirical finding sharply contradicted the conventional wisdom and policy advice many had taken to follow from neoclassical growth theory. The hoped-for reconciliation was that by measuring accurately enough the factor inputs – accounting for improvement in quality of capital and labor – this 'Solow' residual would be diminished.

By contrast, more modern work favors the first interpretation of TFP, that is, it is correctly viewed as enhancing the productive potential of an economy. Thus, economies with large TFP are considered high-growth, high-performance economies. The research focus has shifted from trying to minimize measured TFP to trying to understand its evolution, typically in terms of its being driven by science and research and development (R&D).

Another important idea arose from this early work on measuring economic growth: convergence, or the tendency for economies not already on the steady-state path to approach it. Stated more fully, the neoclassical growth model implies that capitalist economies where capital and labor are rewarded their *marginal products* – the contributions each make, on the margin, to final output – are economies that are stable around their steady states. If an economy is not already at steady state, it has a tendency to go there. Economies relatively poor have a tendency to converge to, or catch up with, those relatively rich.

Penn World Table (PWT): Measuring the Income Variation *across* Countries

One of the primal challenges that growth empiricists encountered is the lack of homogenous data that are comparable across countries. Difficult as it initially was to compile systematic national income accounts for even the advanced countries, obtaining comprehensive and comparable data across countries was becoming more complex. This task has been accomplished only two decades ago (Summers and Heston, 1991) to a degree where researchers can meaningfully compare incomes and therefore economic growth across countries.

Because different countries collect and report income data in their individual, respective currencies, cross-country comparisons can be made only after converting national incomes to a common basis. To achieve this, one possibility is to use official current exchange rates to convert national currency figures into numbers denominated in some single currency. However, such exchange rates are highly volatile, and need not always accurately reflect the purchasing power, or the command over real resources, of the respective national currencies. Importantly, currency exchange rates cannot reflect the prices of nontradeable goods and services. To the extent that nontradeables are relatively lower priced in poorer countries, conversion using official exchange rates *underestimates* the incomes of relatively poor countries, and thus exacerbates the true gap between rich and poor.

As just one example, consider the following. Even though between 1985 and 1990, Asia was the world's fastest growing region, its share of world GDP – calculated using official exchange rates – fell from 8 to 7%. The reason for this is that Asian currencies depreciated sharply against the US dollar in this 5-year period. In this instance using exchange-rate adjusted national incomes disguised (and indeed misled on) actual changes in economic performance.

Summers and Heston (1991), in collaboration with the United Nations, constructed rescaled national incomes for a broad cross-section of countries. They used a *purchasing power parity* (PPP) correction to overcome the measurement difficulty just described. Taking into account prices on close to 700 individual items – traded and nontraded – across different countries, and then adjusting for differential spending patterns, the Summers–Heston data provide one of the most reliable indicators to date, allowing comparison of economic growth across countries. These data have now been used in over 1000 empirical studies on economic growth.

Allowing cross-country comparisons has opened up striking new questions in both the measurement and theory of economic growth. Using 1993 official exchange rates, Switzerland was the world's richest economy; Tanzania, the world's poorest. The ratio of per capita incomes between them approached an incredible 400. By contrast, when PPP-corrected and averaged across the last 5 years of the 1980s to smooth out short-run fluctuations, the ratio between richest and poorest economies (now the US and Chad, respectively) falls to a little over 40. This latter number accords better with less formal evidence and with casual observation on differing costs of living. However, even though PPP correction has reduced the dramatic disparity between rich and poor across the world, the divide obviously remains considerable.

The Summers–Heston data reveal the following: between 1960 and 1989 world per capital income grew by 2.25% per year. Averaged over the 5 years 1960–64, per capita income at the bottom 10th-percentile point (in the cross-section of countries) was 0.22 times the world average, with the 90th-percentile point 2.70 times the world average (Quah, 2001). The 90:10 ratio was, therefore, 12. Almost three decades later, averaged over 1985–89, per capita income at the bottom 10th-percentile point had fallen to 0.15 times the world average while the 90th-percentile point had risen to 3.08 times the world average. The 90:10 ratio thus nearly doubled over this period of high average growth worldwide. More detailed study of the growth dynamics in this post-World War II cross-section of countries has revealed, not just a widening of income disparities across rich and poor, but also an emerging polarization, with the middle-income group of countries dwindling in number (Quah, 1997a).

This finding, that in the post-War era, poor economies do not obviously catch up to the rich, has its interpretation disputed by research arguing that, provided one conditions on the appropriate indicator variables – investment and schooling, in particular – then convergence does occur. That kind of convergence, however, is no longer between rich and poor, but

is convergence of each economy toward its own specific steady-state growth path (i.e., conditional convergence). Hundreds of auxiliary variables have been suggested in these cross-country growth and convergence studies as appropriate alternative or additional conditioning variables (see, e.g., the compilation of studies in Durlauf and Quah, 1999). *Absolute* convergence (i.e., countries progressing to a single worldwide level of output) has been documented clearly only recently by Rodrik (2013), but only within the manufacturing sector.

Over time, the Summers and Heston (1991) data set has been updated and evolved into what is now called PWT. Despite its widespread usage, recently PWT has been subject to criticism. Studies by Johnson et al. (2009, 2013), Ciccone and Jarociński (2010), and Katayama and Ponomareva (2010) indicate that existing findings based on the earlier versions of the PWT in the literature significantly vary with the new versions of it. Hence, Feenstra et al. (2013a) revealed version 8.0 of the PWT that addressed the sensitivity to earlier versions. Version 8.0 of the PWT is – arguably – the best available cross-country data set providing a set of national accounting on relative levels of real GDP, capital, trade, and productivity covering 167 countries between 1950 and 2011. At least three improvements have been made in version 8.0: multiple PPP benchmarks, incorporating novel estimates of relative prices for exports and imports, finally new measures of capital and productivity (*see* Feenstra et al., 2013b).

Inequality: Measuring the *within* Country Variation of Income

As measuring economic growth has continued to focus on progressively fewer observable variables, an implicit tension has correspondingly sharpened: if welfare is proxied only by average income, then income inequality – or more generally, the distribution of income across people – might be unobserved worsening to where an average seriously misleads as an indicator for the economic welfare of the population overall.

The Kuznets (1955) curve describes a key empirical regularity between national income and inequality: Cross-sectionally across economies, inequality is low when per capita incomes are low, increases at moderately higher per capita income levels, and finally falls again at the very highest levels of per capita income. Put differently, the relation between inequality and levels of development is an inverted-U. This early finding suggested to many researchers the possibility that, indeed, economic growth might disadvantage the very poor, due to increases in inequality.

Reverse relationship from inequality to economic development (in particular, growth rate) rate has yet been another focus of interest. Researchers argued that inequality is taxing on economic growth due to redistribution it requires, borrowing constraints it imposes on individuals in the lower end of the distribution, sociopolitical instability it causes, and disincentives it generates. Empirical research found mixed evidence for this relationship, with negative association when variation is considered across countries and positive relationship within a country over time. Importantly, the income inequality data collated by Deininger and Squire (1996) included immensely useful information on income Gini coefficients. This data set was recently updated and standardized by Solt (2009).

Ideas – Science and Technology

Observing that country disparities are large and growing, that is, that convergence is not happening, and that so much of economic growth is due to TFP, has motivated some researchers to investigate models of *endogenous technological change* (One notable exception is Mankiw et al. (1992) who argued that taking into account *embodied human capital* – the quantity of schooling embodied in the labor force – suffices to explain both observations.).

In work on endogenous growth theory, TFP is no longer taken to be exogenously given. Instead, economic theory is used to shed light on the incentives and forces shaping TFP's evolution (Aghion and Howitt, 1998; Grossman and Helpman, 1991; Romer, 1990). The problem of explaining cross-country disparities then becomes one of understanding the dynamics of cross-country technology dissemination (Coe and Helpman, 1995; Helpman, 1993). This work predicts that knowledge inputs – scientists and engineers, R&D, patents, knowledge spillovers, ideas – drive economic growth. The key empirical findings are twofold: First, significant spillovers occur across countries, so that worldwide knowledge accumulation drives worldwide economic growth. Second, country-specific knowledge stocks, resulting from that country's own R&D, do matter importantly, and help explain each country's pattern of economic growth.

The hypothesis of knowledge-driven economic growth, while suggested by the logical sequence of earlier measurements and theoretical developments, remains controversial. For one, many observers consider it implausible that the poorest economies – those in sub-Saharan Africa, say, in the latter part of the twentieth century – are poor because they do not do enough scientific research. This, however, is an overly literal interpretation of knowledge inputs. The ability of people in different economies to absorb and economically exploit scientific developments or even just best-practice production techniques obviously differ. The question then becomes one of incentives to use ideas – why do the very poorest economies not use frontier technologies to raise the productivity of factor inputs? The economics of creating and disseminating ideas, or *intellectual property* more broadly, are subtle; so too, but much less studied, the economics of using ideas.

However, even in the richest economies, empirical evidence is ambiguous on knowledge-driven economic growth. US scientists and engineers employed in R&D grew fivefold from 200 000 in 1950 to over 1 million in 1990; the growth rate of US GDP failed to increase by anything remotely comparable over this period (Jones, 1995).

Structural Drift: Manufacturing to High Value-Added Services

The more recent focus on measuring economic growth using just changes in per capita income has de-emphasized the evolution in industrial structure of economies as growth

proceeds. By contrast, research such as that in Kuznets (1966) consistently documented such basic changes. Quah (1997b) has noted that such structural drift continues, away from manufacturing, toward high value-added intangible services.

Over the nineteenth century, as economies grew, their industrial composition shifted away from an emphasis on rural agriculture, and toward manufacturing and urbanization. Economic activity became progressively more markets-based, so that traditional informal, nonmarket work at home was replaced by formal employee arrangements. Education became more institutionalized; foreign commerce increased; and natural resources were relied on progressively less.

Geospatial Income Measures: Disaggregating the Aggregates

Most of the income measures are aggregated at the national level, and in consequence, spatially disaggregated data sets were either nonexistent or publicly unavailable until recently. Given the advent of geographic information system, macroeconomists start exploring new possibilities of constructing disaggregated national income measures. One of the successful spatially enabled platforms for economic data is the geographically based economic data *(G-Econ)*, a research initiative at Yale University that is devoted to developing a spatial data set on economic activity covering most of the countries in the world (*see* Nordhaus et al., 2006). In particular, the current data set (G-Econ 4.0) provides 'gross cell product (GCP)' for 1990, 1995, 2000, and 2005. GCP is measured at a 1-degree longitude by 1-degree latitude resolution at a global scale, which includes 27 500 terrestrial observations (i.e., cells). In addition to GCP, the G-Econ data set provides other key demographic and geophysical variables – e.g., climate, physical attributes, location indicators, and population.

More recently, Henderson et al. (2011) studied a satellite-based night-time data set covering 1992 to 2009, which is originally provided by the US National Oceanic and Atmospheric Administration's National Geophysical Data Center. They hypothesized that the brightness of visible lights that are laminated at night is strongly associated with both population density and income per capita. They explored the possibility to what extent lights data can augment or entirely replace data on GDP. They recognized several caveats in using lights to measure income. For instance, it is not obvious that economic activities can be completely traced by the amount of light emanating from the earth's surface. Lights are not laminated constantly across time and space. Furthermore, measuring the visibility of true light by the satellites remains imperfect because of climatic variation – e.g., humidity and reflectivity – across regions.

In minimizing the measurement error, Henderson et al. (2011) have taken a series of measures. For example, observations affected by forest fires and auroral activity between the northern and southern lights are removed both manually and using frequency filters. Such data-cleaning measures maximize the chance of capturing mostly man-made light, leaving all other natural lights out of inclusion into the data set.

This lights data set would have a very significant contribution in understanding the *within* country growth variation. The conventional data sources – e.g., PWT – do not provide any disaggregated level data set to measure economic activity at subnational or local level. As much of the significant variation in economic growth may take place within – rather than across – countries, the night lights data open a window of opportunity that allows the growth empiricists to set aside this limitation.

Economic Growth Measures: The Way Forward

Measuring economic growth is an intricate and subtle exercise. It has a scope that can be large and unmanageable. In practice, the history of measuring economic growth has been one of intimate interplay with economic theorizing, leading from improvements in the accuracy and relevance of growth data, to hypotheses on the critical sources of economic growth, to explaining deep changes in the structure of national economies.

TFP, previously a measurement residual to be minimized, has since been reinterpreted, and has emerged as the key driver for economic growth. Ideas – scientific and engineering knowledge, R&D, expertise – constitute the prime candidates for explaining TFP, but the supporting empirical evidence remains weak.

Abstract

Economic activity is human activity, and economic history is the historical study of the economic aspects of human existence. This article presents an overview of the aims and methods of economic history, discusses its position between the social sciences and the humanities, and highlights some current research agendas. The primary focus of the piece is on the historical and theoretical traditions of the discipline, and the lasting impact of methodological changes that occurred in the mid-twentieth century associated with the 'new economic history.'

Defining Economic History

Economic history is neither a branch of mainstream economics nor a branch of intellectual history relating to the history of economic thought. In basic terms, economic history (*histoire économique* in French, *Wirtschaftsgeschichte* in German, *jinji shi* in Chinese, *kaizái shi* in Japanese) is the historical study of the economic aspects of human existence. The broad intellectual range of the discipline enables it to extend beyond purely economic themes (such as the organization of production and distribution, the relation of state and industry, aspects of trade and commerce) and so consider, among other things, inequality, living standards, welfare, social transformation, science, technology, and education. With its focus on mankind's existence in a world of innovation, growth, and development, economic history is a discipline whose core principles possess a powerful human dimension.

This is a short article on a large topic relating to the aims and methods of economic history. Central to this discussion is the social scientific formalization of economic history in the mid-twentieth century. This marked the transition of the discipline from traditional economic history to the 'new' economic history, and so rooted the discipline in the methodology of economic science. In doing so, it ignited lasting 'creative tensions' between scholars trained in historical method and those trained in economic theory.

Origins and Development

The origins of economic history can be traced to the work of the early practitioners of political economy and social science: writers such as Smith, Marx, and Weber all employed historical evidence in their study of economic practices, social phenomenon, and the capitalist system. As a distinct academic discipline, the origins of economic history lie in late nineteenth-century German, British, and American scholarship and the construction of a methodology with strong links to established themes of general history (i.e., political, ecclesiastic, and legal histories), the work of the German historical school (dismissive of abstract economic theory and focused on the impact of variation in economic development), and the institutional economics associated with Thorstein Veblen. Its position as a subject of scholarly enquiry and academic teaching expanded steadily in the nineteenth century and was firmly consolidated by the early twentieth century with the creation of specific academic posts and later specialized journals – the *Economic History Review* (first published in Britain in 1927), the *Annales d'histoire économique at sociale* (first published in France in 1929), and the *Journal of Economic History* (first published in the United States in 1941). During this period, the interests of economic historians focused on comparative historical research to investigate the broad issues of economic life. Such studies incorporated some quantitative analysis, but little attention was given to employing explicit economic theory in analyzing past economic events or processes. As a consequence of these developments, economic history by the mid-twentieth century had developed as a discipline largely separate from economics.

The Emergence of the New Economic History

The key developments and refinements of economics theory that emerged by the end of the Second World War were fueled by new approaches to the study of the aggregate economy, growing interest to the mechanisms of economic growth, and the better availability of long-run economic data. By the 1950s, new attention to the subject of modern economic growth led many economists, particularly in the United States, to explore the long-held assumptions and conclusions associated with the older generation of economic historians. The conclusions of these younger, economics-trained scholars were damning: the quality of early economic history research had been undermined by largely descriptive, illustrative, and institutional approaches; quantitative analysis lacking rigor; and little attention had been paid to the application of economic theory to historical data.

It is here that we find the principles that propelled the cliometric revolution (from the Latin: *Clio*, the ancient Greek muse of history; *metrics* meaning measurement), so leading to the social scientific formalization of economic history between the 1950s and the 1970s. Cliometrics – otherwise known as the 'new economic history' or 'econometric history' – provided an innovative methodology that emphasized (1) a strong focus on the precision and formalism of scientific method in order to elevate the discipline of economic history to a scientific level,

and (2) the systematic application of mathematically formalized economic models and quantitative techniques to the study of historical economic phenomenon. Belief in the potential of these methodological developments, most notably in evaluating and challenging existing historical interpretations and scholarship, is palpable in the following quote by the American economic historian, Douglass C. North, published in the early 1960s:

> A revolution is taking place in economic history in the United States. It is being initiated by a new generation of economic historians who are both sceptical of traditional interpretations of U.S. economic history and convinced that a new economic history must be firmly grounded in sound statistical data. Even a cursory examination of accepted 'truths' of U.S. economic history suggests that many of them are inconsistent with elementary economic analysis and have never been subject to – and would not survive – testing with statistical data.
>
> North (1963): 128–129

The speedy acceptance of this new form of economic history among economists owed much to its focus on mathematical methods and rigorous quantitative techniques. Institutional structures reinforced the distinct character of this intellectual movement, famously through a special gathering held in Massachusetts in the autumn of 1957 and conferences and seminars at Purdue University in West Lafayette, Indiana. From these emerged the style, tone, and research agenda – primarily related to American economic history – that came to define the 'new economic history' for many years. Notable examples of this early work included Alfred H. Conrad and John R. Meyer's groundbreaking study of the profitability of slavery in the ante-bellum South (Conrad and Meyer, 1958), and Robert Fogel's (controversial) use of counterfactual analysis to explore the contribution made by the railways to American economic development in the nineteenth century (Fogel, 1964).

The overall impact of this new research agenda marked, as William Sewell Jr. has noted, "a move from economic history as the study of the forms of economic life to economic history as the historical study of the determinants of national economic growth" (Sewell, 2010: 152). It was now economic historians trained as economists, utilizing statistical techniques and mathematical models, who seized the commanding position in the discipline with their attention focused on investment, technological development, total factor productivity growth, historical national accounts, and long-term patterns of economic change.

It should come as no surprise that this new, quantitative-analytical study of economic history attracted numerous criticisms. By far, the most famous example of this came with the publication of Robert Fogel and Stanley Engerman's dramatic reinterpretation of the viability of American slavery in *Time on the Cross: The Economics of American Negro Slavery* (Fogel and Engerman, 1974).

The standard critique of the 'new economic history,' which emerged in the 1960s and continues to this day, concentrated on the degree of abstraction applied by cliomatricians and the construction of historical narratives that correspond to the conceptual framework of conventional (neoclassical) economics. Critics argued that this tendency to view history purely through the prism of abstract models raised numerous methodological questions, ranging from the ease by which investigators could select independent variables in order to condition the results of regression analysis through to the dangers inherent in counterfactual propositions.

A distinctive feature of the 'new economic history' was the employment of the counterfactual hypothesis method. The basic principle here was simple: in order to establish the impact of a particular factor, it was necessary to consider what the situation would have been in the absence of that factor. Such questions could be asked through the use of economics theory, with the specification and criteria of the economic model serving to construct counter-to-fact conditions. Yet the end result, in the eyes of many, was to produce mere 'fictions' rather than detailed historical interpretations. As an example of this, we may note Fritz Redlich's criticisms of Fogel's use of counterfactual analysis in exploring the impact of the railways on American economic growth (Redlich, 1965).

The Search for Balance

From the 1970s onward, criticism and dissatisfaction from within the ranks of scholars associated with the 'new economic history' began to suggest a new way forward. Here the criticism was that while of the systematic application of static neoclassical analysis had destroyed the explanations of an older generation of economic historians, it provided limited answers and failed to construct clearer explanations of long-run economic change. To quote Douglass C. North:

> It is the systematic use of standard neo-classical economic theory which has both provided the incisive new insights into man's economic past and also serves to limit the range of enquiry.
>
> North (1974): 1

There was now the realization for the need to provide a deeper examination of the structure of economies, the intricate interactions of economic and social forces, and the formal and informal rules that governed the ways people had lived their lives. In searching for balance, economic historians were therefore prompted to construct a broader analytical approach in order to evaluate the importance of factors such as entrepreneurship, cultural heritage, the evolution and impact of institutions, property rights, contract law, and government.

Thus, by the 1980s, it has been recognized that the study of economic history could not be practiced by rigid adherence to a methodological apparatus focused purely on quantitative techniques and standard economic analysis. Yet a more holistic form of the discipline – operating through a renewed framework that embedded economic development in the social, cultural, and political environment – clearly echoed themes that had been prominent within traditional economic history before being systematically ignored in the wake of the cliometric revolution. It was that move to enrich the study economic history from the 1980s onward, through the reintegration of a more traditional historical methodology, that has led one critic to identify the rise of cliometric economic

history as, ultimately, a "revolution that bit its own tail" (Drukker, 2006).

Historical Economics

The extreme application of the new methodology associated with the 'new economic history' led to the emergence of what may best be described as 'historical economics.' This is a variant of economic history as practiced by economic-trained economic historians whose objective is to use history to either illustrate theory or test hypothesis derived from theory. This fundamentalist form of cliometric/econometric history, with its research program derived from, and conforming to, the standards and practices of modern economics, suggests to its practitioners that the discipline continues to develop a rich understanding of modern economic growth. The reality, however, is that this formulation of economic history – with its focus on the utilization of historical time series as a means of testing sophisticated theoretical models – serves as a very poor basis on which to study the economic aspects of human existence. Indeed, 'historical economics' ultimately diminishes the richness of economic history by relegating it to little more than a branch of applied economics. Yet it must be recognized that 'historical economics,' although practiced by some scholars, is far from being the standard form of economic history that exists in the twentieth-first century.

The Future of Economic History

Where does economic history stand today? It is clear that, since the end of the Second World War, economic history has witnessed the dominance of economics-trained/based economic historians over history-trained/based economic historians. This is impossible to deny – the modern form of economic history is supported by the application of economic theory and quantitative techniques, and the majority of economic historians are to be found in leading PhD-producing economics departments. Although never achieving the same degree of dominance among European economic historians compared with their American counterparts, the successes of the 'new economic history' were formally recognized in 1993 with the awarding of the Nobel Memorial Prize in Economics to Robert Fogel and Douglass C. North.

It is certainly true the current status and character of economic history holds a very lowly position within the humanities. In briefly examining this issue we may note two key themes. The first concerns the activities of the early cliomatricians (in the 1960s and 1970s) who oversold their new methodology to historians by reinterpreting established interpretations through a blinding barrage of esoteric economic and quantitative methods. A second theme concerns recognition of important developments within the study of history since the 1980s, including the rejection of economic determinism associated with Marxist analysis, the compartmentalization of history into subdisciplines focusing on specific themes and case studies, and the impetus of the 'cultural turn' that emphasized literary and linguistic analysis over quantitative analysis. Thus, whereas economic history deals with the (dirty) world of trade, commerce, industrialization, and growth, the research agendas of social and cultural historians from the 1980s onward have increasingly focused on topics such as race, gender, identity, consciousness, and public memory. Both of the above themes – lasting reactions to the attitudes of the early practitioners of the 'new economic history,' and developments in the methodology of history since the 1980s – have made historians antipathetic to the study of economic history. From the perspective of the modern (cultural) historian, researchers in the area of economic history are easily dismissed for employing an inappropriate, narrow methodological framework that strips humanity from the historical narrative! Irrespective of the fact that economic history has moved beyond the strict methodological principle associated with the 'new economic history' (and so focusing on the relations between past economic events, institutions, social structures, and cultural change), the subject – indeed, it could be argued, anything connected with economic issues! – remains heavily tainted in the eyes of many historians.

Yet set within the context of the social sciences, economic history remains a rich and active field of investigation and it cannot be denied that the twenty-first century form of the discipline encompasses a variety of methodological approaches. While it is impossible to predict the future direction of research programs, it is evident that current practitioners are consciously working to strike a balance between formal theory (drawn from disciplines across the social sciences, and not just economics), quantitative methods, and historical techniques. The geographic range of current research now extends beyond the traditional areas of North America and Western Europe to include

- the history of economic development across medieval, early modern, and modern time periods;
- the history of debt, taxation, and credit relations;
- the causes and impact of financial crises within capitalist societies (clearly a growing area of interest since the global crisis of 2008);
- detailed case studies of different sectors and processes, including agriculture, demographic change, transport and communications, labor markets, education, and urbanization;
- the study of national economies/societies within the wider framework of global economic development and debates surrounding economic globalization;
- the Great Divergence of living standards between Asia and Western Europe (and, by extension, the emergence of Asian economic history as major area of research);
- quantitative analysis of the relationship between economic development, living standards, and biological well-being (otherwise known as anthropometric history); and
- debates connecting economic growth with environmental degradation (and hence the growing attention to environmental history).

Even the most cursory examination of these topics will show that the modern focus of economic history is definitely *not* concerned with the simplistic application of econometric methods to historical data!

It was noted in the introduction to this article that economic history possesses a powerful human dimension. Economic

activity is human activity, and it is this core principle that, as Patrick O'Brien has highlighted, makes economic history "too fundamental to be virtually ignored by historians and too complex to be left to economists with their shortcuts into cross-country multiple-regression" (Lyons et al., 2008: 443). Similar themes are reflected in comments by Pat Hudson, who has argued that economic historians today are presented with opportunities to "critique the narrow purview of much contemporary economic theory" as well as "ambush the many cultural historians who appear to have forgotten what the economy is" (Hudson, 2010: 249). The great opportunities available to economic historians stem, therefore, from the position of the discipline between the cultures of the social sciences and the humanities, and hence the continuing importance their contributions can make to the historical study of economic life.

Abstract

The term 'cliometrics' was coined in the 1950s, referring to a self-conscious movement to revolutionize economic history by incorporating quantitative methods and explicit models into the study of past phenomena. The new approach swept to dominance between 1955 and 1975. Subsequently, economic historians began a return to older interests in institutions, culture, and technology. Prominent figures argued that the study of well-established market systems constituted a narrow approach, not well chosen to support a distinctively historical contribution to economics. Although the renewed interest in institutions is a return to earlier terrain, the new incarnation is firmly lodged within the parent discipline of economics.

Quantitative Economic History in the United States

Economic history is a hybrid discipline, concerned with recording and interpreting the economic events of the past. It should not be confused with the 'history of economic thought', the study of the intellectual history of economics as a discipline (*see* Economics, History of). Although the practice of compiling historical statistics goes back to the nineteenth century if not earlier, the term 'quantitative economic history' refers to a self-conscious movement dating from 1950s to 1960s, then known as the 'new economic history' and more recently 'cliometrics', which set out to revolutionize the field by incorporating explicit economic analysis and quantitative methods into the study of past economic events. In subsequent decades, practitioners have extended and redirected this agenda, by drawing upon diverse branches of economic theory to analyze the historical evolution of market and nonmarket institutions, technology, preferences, and other features of economic life commonly taken as exogenous by mainstream economics. The resulting literature stresses the influence of historical experience on ensuing economic patterns, an intertemporal linkage known as 'path dependence'. This article traces the main tendencies in quantitative economic history over the past half-century, though it is by no means a comprehensive survey.

The Origins of Economic History

Recognition of economic history as a distinct subject is traceable to the consolidation of British neoclassical economics at the turn of the twentieth century, under the towering influence of Alfred Marshall and his Cambridge successor, A.C. Pigou. The analytical core of the dominant school held that economies tended toward 'long-run equilibria' that were independent of initial conditions (though Marshall himself was by no means dogmatic about this doctrine in practice). Having lost out in the struggle for the disciplinary identity of economics itself, the 'historical school of economics' emerged at that time as a reaction against the neoclassical paradigm and the laissez-faire program with which it was associated. Drawing ideas and inspiration from the 'German historical school' of Gustav Schmoller and Friedrich List, early historical economists emphasized the virtues of inductive studies as contrasted with the deductive or axiomatic approach. Methodological preferences were reinforced by their affinity with 'neomercantilist' policies, including promotion of national industries, social reforms, and the regulation of enterprise. The organization of economic history as an academic field in Britain was prompted as much by a search for refuge as by the emergence of a distinctive research agenda. William James Ashley, first president of the Economic History Society at its founding in 1926, lamented: "the theoretical economists are ready to keep us quiet by giving us a little undisputed garden plot of our own; and we humble historians are so thankful for a little undisputed territory that we are inclined to leave the economists to their own devices" (quoted in Koot, 1987: p. 7).

Similar tensions persisted in the United States, but the separation between economics and economic history was slower to develop. The inductive approach of the 'institutional' school associated with such figures as John R. Commons and Thorstein Veblen was dominant within labor economics and in other parts of the parent discipline, displaced only by the rise of Keynesian economics in the 1930s and 1940s. In the same era, 'progressive' historians such as Frederick Jackson Turner and Charles Beard put economic conflict and change at the center of their 'economic interpretation of history'. Although neither of these groups would be recognized today as economic historians, they did provide outlets for those dissatisfied with the deductive methodological approach. Thus, the (American) Economic History Association was founded only in 1940, and lacked the ideological identity and fervor of its British counterpart.

Between the 1930s and 1950s, a few exceptional figures such as Carter Goodrich could have a significant impact on both economics and economic history. But the majority of Economic History Association (EHA) members were historians, whose works made little use of economics and had little influence on the thinking of economists. The same could be said for entrepreneurial history, which flourished for a time at the Harvard Center for Entrepreneurial History, under the leadership of Arthur H. Cole. In retrospect, many of the rich descriptive studies from this era have lasting value, perhaps best reflected in the monographic series entitled *The Economic History of the United States*, published between 1945 and 1962. But as economics became increasingly analytical and quantitative, economic history at the time appeared to be something of a stodgy backwater.

The Rise of Quantitative Economic History

Two decades after the World War II saw a significant expansion of economic history within economics, much of it was quantitative in character. This was mainly an American development, and largely (though by no means exclusively) focused on the economic history of the United States. The immediate stimulus was the new postwar interest in economic growth. Following the lead of Simon Kuznets, father of the national income accounts, a new generation of economic historians sought to extend the statistical record of the American economy back to its origins early in the nineteenth century, drawing upon the rich potential of the decennial census and making ingenious use of other diverse archival sources. The major results of these efforts were presented in landmark volumes published by the National Bureau of Economic Research (Parker, 1960; Brady, 1966). Estimates developed by Robert Gallman suggested that growth in the United States had reached modern rates by the middle of the nineteenth century, and should not therefore be seen as the consequence of political upheavals at the time of the Civil War (as hypothesized by Charles Beard). Adapting Gallman's estimates into a regional framework, Richard Easterlin showed that the slave economy of the South also shared in the growth acceleration, though per capita income in that region was some 25–35% below the national average.

A second and more controversial thrust was the deployment of tightly constructed deductive models to address specific hypotheses about this statistical record. The advent of this 'cliometric' approach is often dated from the publication in 1958 of 'The Economics of Slavery in the Ante-Bellum South' by Alfred H. Conrad and John R. Meyer (reprinted in Fogel and Engerman, 1972). In this article, Conrad and Meyer set out to settle a perennial debate over the 'profitability of slavery', by treating slaves as a form of capital and posing the question as an explicit rate of return on investment calculation. Their conclusion was that investments in slaves were just as profitable as alternatives like railroad bonds. Other studies tackled broader questions about the origins of growth and the impact of government policies. Douglass North's *The Economic Growth of the United States, 1790–1860* (1961) interpreted the acceleration after 1815 as a dynamic response to the potential of expanding markets, primarily through interregional specialization and trade. Robert Fogel's *Railroads and American Economic Growth* (1964) and Albert Fishlow's *American Railroads and the Transformation of the Ante-Bellum Economy* (1965) generated comprehensive estimates of the contribution of railroad construction to national economic growth, by posing explicit historical counterfactual circumstances within an analytical framework. Both the methods and the conclusions of these provocative works were the subjects of intense academic debate for many years after publication.

One strand of this discussion represented a reaction by 'old economic historians' against attempts to subsume historical complexity into what they regarded as hypothetical and unrealistic abstractions. A second strand, however, came from within the economics discipline, reflecting dissatisfaction with the limitations of standard resource-allocation models as the working tools for structuring research in economic history. In 1972, two collaborative efforts summarized the major results of the New Economic History as of that date (Davis et al., 1972; Fogel and Engerman, 1972). *American Economic Growth* was a multiauthor collaboration organized around economic sectors; *The Reinterpretation of American Economic History* was an eclectic collection of essays addressing largely microeconomic issues in the new quantitative-analytical style. The editors of a retrospective on the cliometric revolution remark: "Today a large share of the economic history profession in North America consists of the intellectual children and grandchildren of the first generation of cliometricians who reported on their pioneering accomplishments in these volumes" (Lyons et al., 2008: p. 21).

Signs of growing unrest were also evident, however, and in retrospect these volumes have the character of closing chapters in a methodological cycle that had largely run its course by that year. This interpretation may be elaborated by a review of two major research areas.

The Economic Analysis of Technological Change

Economic historians of all stripes had no difficulty agreeing that a central component of economic growth was technological change, broadly defined to include organizational innovations and the diffusion of existing techniques, in addition to the more famous 'inventions' that have long been standard fare in textbooks. But the dominant tradition in economic analysis has long regarded technological change as exogenous, not part of the domain of a discipline specialized in analyzing the *implications* of such change for the economy. One might reasonably hope, therefore, that quantitative economic history would be able to say more about the timing, pace, and direction of particular historical technologies, if not to uncover historical laws of motion for technological change in general.

In the context of American economic history, these questions were brought to the fore by a landmark book published in 1962 by the British economic historian H.J. Habakkuk, *American and British Technology in the Nineteenth Century*. Habakkuk hypothesized that American industry pioneered the development of capital-intensive methods as compared to Great Britain, in response to the scarcity of labor relative to land in the United States. This apparently straightforward thesis subsequently proved exceptionally difficult to capture analytically or to confirm empirically. An extended stream of contributions by Peter Temin, Robert Fogel, Nathan Rosenberg, Paul David, Alexander Field, John James, David Hounshell, Kenneth Sokoloff, Zorina Khan, and Ross Thomson among others, succeeded in elaborating many characteristic features of the technologies emerging as an American national specialty in the nineteenth century. In comparison to the British, American techniques were not only capital-intensive. They were also resource-using; faster-paced; skill-saving (at least for traditional craft skills); and adapted for long production runs of standardized final products. As useful as this accumulated descriptive knowledge may be, the question remains: what sort of economic analysis would allow the quantitative economic historian to come to terms with the origins and nature of this list of characteristics?

The long-running debate over the 'labor scarcity paradox' brought out most clearly that so long as the analytical framework was defined by standard neoclassical analysis, the subject matter would be transmuted into the language of 'relative factor abundance' and substitution, terms derived from the

assumption that a 'production function' is given by technical factors. Within this constraint, the economic historian was powerfully driven toward the exercise of rationalizing observed historical choices. The impulse was observed most clearly when the choice-of-technique question was transported to the other side of the Atlantic, and cliometricians assessed the popular indictment of British entrepreneurs for their reluctance to adopt American methods. Virtually without exception, the conclusion was that British choices were entirely appropriate responses to prevailing factor prices and market conditions. Although this verdict may be valid, the uniformity of results gave rise to doubts about whether it constituted an authentic inference from historical evidence, or merely an assumption imposed on the evidence by the economist's worldview.

This approach to technology proved unduly constraining for a number of reasons. As subsequent research has demonstrated, the 'factor endowments' taken to be fundamental determinants were themselves not really exogenous, being subject to influence by policy and by technology itself as it unfolded through time. In agriculture, Paul Rhode and Alan Olmstead (2008, 2011) show that the expansion of American farmland required not just transportation but new knowledge, including new crop varieties and cultivation practices adapted to the soils and climate of western regions. In other words, the growth of the productive input 'land' was itself the result of learning and knowledge accumulation, so that the observed constancy of yields per acre should not be understood to indicate an absence of 'technological progress'.

In industry, the large inflows of unskilled immigrants to the United States are most readily explained by the growth of industrial jobs adapted to that type of labor, a result in other words of an attribute of the new technology. Even American abundance of mineral resources – coal, iron ore, copper, petroleum, and many more – turn out on closer inspection to have been more the *result* of technological development and capital investment than its cause (David and Wright, 1997). To a significant extent, minerals constituted a 'knowledge industry' even in nineteenth-century America. As such, its development was part of the broader evolution of national technology, or learning, whose evolution was itself the phenomenon to be explained.

The Slavery Debate

No topic tested the limits of deductive economic history more fully than slavery. Conrad and Meyer (1958) set out to measure the 'profitability of slavery', and thereby to test the thesis that slavery would have died out for economic reasons, in the absence of the Civil War. Among others, Yasuba pointed out that because slave imports were ended by legislation in 1807, a more appropriate measure of the private economic viability of slavery was the level of 'capitalized rent' embedded in the price of slaves – high and rising on the eve of secession, according to Yasuba's estimates (1961, reprinted in Fogel and Engerman, 1972). The 'profitability' finding is best understood as an indication that slave prices approximately capitalized the expected stream of future returns, which may be taken as evidence that 'capitalist' motivations were dominant in the operation of the slave system. The achievement of consensus around this broad proposition, however, redirected attention toward more difficult and challenging historical issues, such as the long-term consequences of slavery as a mode of social organization.

This was the setting for the appearance in 1974 of *Time on the Cross: The Economics of American Negro Slavery*, by Robert W. Fogel and Stanley L. Engerman. Fogel and Engerman went well beyond the previous consensus, presenting total factor productivity calculations implying that slave plantations were as much as 35% more efficient than free family farms. Not only was the slave system highly productive, but also the authors went on to assert that material and social conditions among slaves were far better than historians had recognized. Using such indicators as diet, clothing, housing, life expectancy, and family stability, the authors compared the lives of slaves favorably with those of immigrant workers in the northern states. It is hardly surprising that these incendiary claims generated an explosive reaction.

The full range of the ensuing debate cannot be recounted here. As with the response to Conrad and Meyer, one part of the reaction represented traditional historians objecting to the coldhearted nature of the calculations, and the apparently cavalier treatment of the feelings and behavior of the slaves themselves. Another component, however, came from within the profession. Detailed scrutiny of the statistical evidence ultimately led to significant modifications of the relatively benign picture of slavery, most notably in health conditions and family life. It would be mistaken to characterize the alternative views on these issues along simplified dimensions, such as the presumption that historical operators are rational and market oriented. For example, subsequent research suggests that slaves were bought and sold much more frequently than Fogel and Engerman believed, often separating not only husbands from wives, but even mothers from their children. On this count, *Time on the Cross* if anything actually understated the ruthlessly profit-driven character of American slavery.

Debates over empirical evidence are a normal feature of any social science. The dimension of the slavery debates with more enduring import for quantitative economic history concerned the *conceptual* underpinnings of the analysis of slavery, specifically the emphasis on calculations of efficiency in production. Because plantations produced multiple outputs with heterogeneous inputs, it emerged that the efficiency results were highly sensitive to relative values assigned to cash crops (such as cotton) vs food crops (such as corn), and to factors of production (such as farmland of varying quality, or male vs female slave labor). The debate may be followed in David et al. (1976), a subsequent exchange in the *American Economic Review*, and Wright (2006). The deeper issue was whether it was possible, or perhaps whether it was meaningful and historically informative, to separate the calculation of productive efficiency as a technical matter, from the task of locating slavery as a system of property rights in historical time and space. From this perspective, property rights in slaves had a decisive influence on the course of economic development in the southern states, not only on human capital investment, but also on geographic patterns of settlement, transportation infrastructure, and urbanization.

In several respects, the course of the slavery debate highlights the new directions in which quantitative economic history has moved since the 1970s: study of the evolution of institutions; incorporation of political, social, and ideological

dimensions into economic history; and identification of lasting effects of historical phases on later events. These tendencies are well illustrated by the careers of two founding figures of the New Economic History.

The Nobel Prizes

In October 1993, the Royal Swedish Academy of Sciences awarded the Nobel Prize in Economics to Robert William Fogel and Douglass North, noting that "they were pioneers in the branch of economic history that has been called the 'new economic history', or 'cliometrics'." In essence, the two economic historians were cited for helping to launch the quantitative economic history movement. In what must be a rarity among Nobel laureates, at the time of the award both men had moved some distance from the approach for which they were honored.

North's early work in American economic history was both quantitative and analytical. He developed new statistical time series on the US balance of payments, and on the long-term decline in transportation costs. North (1961) drew upon concepts from theories of location and comparative advantage to interpret the quantitative record of regional performance. His first ventures outside American economic history were consistent with this focus on market incentives, emphasizing the role of limited government and secure property rights in explaining the comparative historical performance of nations. By the 1980s, North's range of analysis had broadened considerably, to include *ideology* (including norms and belief systems) as a primary element in comprehending the persistence of order in the world, essential for the effective functioning of markets. North (1990) cast the net even more widely, pointing to the critical economic role of *institutions*, defined broadly to include all "the humanly devised constraints that shape human interaction". This expansion of horizons continued in North (2005) and North et al. (2009), which explore the historical determinants of institutions and the comparative efficacy of societal systems for generating *new* institutions. At least part of North's personal evolution arose from his growing awareness that the effectively functioning market society found in the United States is quite exceptional in a global context.

Fogel's intellectual trajectory was rather different. Both Fogel (1964) and Fogel and Engerman (1974) built sweeping historical interpretations on the results of complex and ambitious quantitative procedures. After 15 years of further research on slavery, Fogel (1989) devoted more than half of his next book to an account of the rise of antislavery opinion in Europe and the United States, emphasizing the force of religious, political, and ideological factors. Fogel wrote: "I began [this research], like many other cliometricians, not because I was especially interested in the history of American slavery, but because an accident of scholarship made the economics of slavery a major testing ground for the application of cliometric methods. Once drawn into the subject, however, it was the substance of the issues that maintained my interest. Although my principal professional expertise was, and is, in the areas of economics and demography, I found myself led down a road that forced me to grapple with the work of colleagues in cultural, political, and religious history" (p. 13). Fogel's interest in subjective and ideological aspects of history persisted through his later quantitative work on historical nutrition and physiology (2000, 2004). It seems safe to say that by the twenty-first century, cliometrics had outgrown the historical naivete of its youth. (Robert Fogel died on 11 June 2013. An appreciative remembrance by former student is Goldin (2014).)

New Directions in Quantitative Economic History

Since the methodological wars of the 1950s through the 1970s, the cliometric revolution has become all but complete within economic history. Most practicing economic historians are now employed in departments of economics, and the majority of articles published in the *Journal of Economic History* deploy econometric techniques. The list of cliometrically oriented journals has steadily expanded in recent decades: for example, *Explorations in Economic History*, *The European Review of Economic History*, and *Cliometrica*. Even the staid British *Economic History* Review is now far more quantitative and economic than in earlier times. Thus, economic history has thrived in its cliometric identity, though diminished by the only partially anticipated consequence that the field has largely disappeared from departments of history.

Although most quantitative economic history accepts economics as the parent discipline, the field remains distinct in its practices and its intellectual priorities. In comparison with their mainstream colleagues, economic historians place greater emphasis on the historically contingent character of economic relationships, deploying a more eclectic range of theoretical models and conceptual tools. Indeed, over the years economic history has become steadily more diverse and expansive in both its methods and its subject matter. Some of these tendencies reflect growing diversity in the composition of the cliometric intellectual community, which now includes many more women and scholars of differing nationality than was true in the 1960s and 1970s. Once almost exclusively an American phenomenon, cliometrics is now also pursued by small but thriving groups in Europe, Latin America, Canada, and elsewhere. Another force for diversification is the expanding range of topics now covered within economics itself, including ecology, law, family, gender, and race, all of which have strong historical dimensions. Since the full range of scholarship cannot be surveyed here, a brief account will be given of two general areas in which historical aspects of economic life seem especially compelling.

Increasing Returns, Path Dependence, and Technology

In 1984, William N. Parker organized a session at the annual meetings of the American Economic Association, on the role of economic history in graduate economics education, the proceedings of which were published in Parker (1986). Among the many spirited defenses of history by such economists as Kenneth Arrow, Robert Solow, Peter Temin, D.N. McCloskey, and others, one contribution proved to be particularly lasting as an illustration of path dependence: Paul A. David's account of the rise and persistence of the QWERTY typewriter keyboard. Although many evidently superior layouts were designed and marketed during the typewriter's post – Civil War diffusion, the standard became 'locked in' to QWERTY by the 1890s,

illustrating the power of historical accident and 'network externalities' to shape the course of technological history. Drawing in part upon theoretical work by W.B. Arthur, David argued that because choices were interdependent – since manufacturers, employers, and typists all wanted to use the same keyboard that others were using – the system never shook off the circumstances of its origin, despite the suboptimality of the equilibrium choice.

The QWERTY story has emerged as a popular metaphor for the proposition that 'history matters' in economic life. The typewriter example and its meaning have been hotly controversial, and its appropriate scope and significance have by no means been settled. But its relevance for quantitative economic history has been to confirm the historical character of the economics of technology. As noted above, the study of technological change had never fit comfortably within the New Economic History. Nathan Rosenberg, a member of the first cliometric generation whose research on technological change diverged from the reigning paradigm, had long been engaged in *Exploring the Black Box* (1994), i.e., trying to understand technological change as it would be perceived and advanced by members of technical communities. Since then, such economic historians as Robert Allen, James Bessen, Claudia Goldin, and Joel Mokyr have elaborated the context-specific factors that have served to encourage, retard, or channel technological progress. The venerable debate on 'American technological exceptionalism' has been transformed by detailed studies of the institutional bases (both formal and informal) for US technology by economic historians such as Ross Thomson, William Lazonick, Kenneth Sokoloff, Zorina Khan, Naomi Lamoreaux, and Petra Moser.

The broad conclusion of this research is not to deny that technology is responsive to incentives – quite the contrary – but to argue that these responses are conditioned by the historical and institutional setting, including the cognitive structures through which knowledge is codified and transmitted. Distinctively historical studies with these features include Lampe and Moser (2010), Saxonhouse and Wright (2010), Moser (2011), Bessen (2012), and Gray (2013).

Institutions and Economic History

In the heyday of the New Economic History, 'institutional' was used as a term of dismissal if not contempt, to refer to old-fashioned descriptive work that lacked theoretical foundations. As the field has evolved, 'institutional' economic history has again become respectable, though in new and more analytical clothing. Indeed, many argue that the study of institutions is at the heart of the case for historical economics. Whereas the parent discipline specializes in the functioning of markets, the domain of the economic historian is the institutional foundations that allow markets to function as they do. These subject areas have become more pressing in light of the varied experiences of formerly planned economies in their transition to market systems.

In its first phase, the so-called New Institutional Economics identified 'institutions' with the property rights, rules and regulations defined and enforced by the state, interpreting institutional change as responses to exogenous shifts in population, technology, or the scope of markets. Beginning with North and Thomas (1973), numerous historical studies examined the implications of these institutions for economic performance, broadly confirming the general proposition that securely enforced property rights are favorable for economic efficiency and growth. Deviations from this pattern are commonly attributed to the influence of special interest groups, with transactions costs standing as barriers to more efficient systems.

Dissatisfaction with this framework gradually began to build, with the realization that the simple cause and effect scenarios took as exogenous much of what was most historically interesting. An essential next step was to broaden the concept of institutions, to include not only explicit and state-enforced rules, but informal and uncodified constraints on behavior as well. To say that institutions are 'constraints', on individual behavior, however, does not mean that they must be seen as having been 'imposed' on the society in question. By analogy to market prices, institutions may be viewed as exogenous to the individuals, yet historically endogenous to the society as a whole. When the underlying conception has been broadened in this way, a natural theoretical framework is provided by game theory, depicting institutions as self-enforcing equilibria arrived at through the interaction of historical players. Avner Greif (2006) has been a pioneer in the application of game theory to historical institutions, using these tools to analyze the bases for the rise of long-distance trade in late medieval Europe.

Greif argues that appropriate historical uses of game theory must be context-specific. In many strategic situations, there are multiple equilibria, implying that outcomes are not uniquely predetermined. Constructing a context-specific model that captures the essence of a situation requires microlevel historical study, to provide the specific details of the model, and to facilitate the task of confronting predictions with historical evidence. Thus, the process has a large inductive component, drawing on cultural, political, and social factors as well as upon economic motivations. Although this specificity may seem to limit the potential scope for application, Greif was able to use these tools to extract sweeping implications from the contrasting cultural beliefs of the Maghribi traders (who used collective social instruments to discipline the behavior of their members) and the Genoese (from whose rule-based system, the Western legal traditions descend). Such institutional evolution often exhibits increasing returns and path dependence, similar to technological systems subject to network externalities.

In many ways modern quantitative economic history has returned to the roots of economic history, in its renewed appreciation of institutions and culture. But there is a major difference. Whereas earlier versions of 'institutional economics' tended to be 'antitheory', stressing the sheer weight of historical reality as contrasted with abstract rationalizations, the newer forms of institutional economic history are firmly lodged within the parent discipline, drawing on frontier developments in economic theory as well as quantitative methods. The ability to deploy more eclectic theoretical tools allows cliometricians to extend their reach into new subject areas that previously were preserves of purely descriptive work. A prominent example would be historical studies of financial markets and financial institutions, which now use theories of information and principle-agent relationships. This line of research returned

to prominence when the financial crisis of 2007–08 undermined faith that these markets are or had become essentially self-regulating. Barry Eichengreen (2012) devoted his 2011 presidential address to the Economic History Association to an exploration of how the historical analogy to the Great Depression of the 1930s shaped perceptions and policy responses many decades later.

The history of labor markets and related institutions – central to the mission of the 'old' institutional economics – has also enjoyed a renaissance, because the roles of norms, prejudices and family relationships are too prominent in this subject area to be ignored. An illustration of this is Claudia Goldin's book on the economic history of American women (1990). The early chapters developed new quantitative evidence on relative wages and labor force participation rates of American women, interpreting two major upward surges (1820–50 and 1890–1930) in terms of supply and demand forces, largely driven by technology. By the latter half of the book, however, Goldin found that 'institutional' aspects of the record were inescapable, from the 'marriage bars' of the 1920s and 1930s – which forced women to resign from jobs upon marriage – to patterns of socialization and peer influence, detectable in behavioral shifts from cohort to cohort across the twentieth century. Reflecting on her own evolution, Goldin wrote: "I began this study more as an economist but have ended with a fuller appreciation of how the distant past affects the present, how norms and expectations impede change, how discrimination can survive even in highly competitive markets, and how slow genuine change can be" (p. viii).

To be clear, an 'institutional' approach to labor economics does not imply a belief in universal historical persistence. If 'lock-in' means that a system no longer responds to incremental changes in incentives, the corollary is that when change does come, it is likely to be sudden and unanticipated; the flip side of path dependence is historical discontinuity. Thus, Joshua Rosenbloom and William Sundstrom (2010) interpret American labor history as a series of 'regimes', apparently stable equilibria interrupted by periods of rapid and often surprising structural change. Stacey Jones (2009) recounts one such episode, the dramatic transformation in social norms and women's higher education between 1965 and 1975. In these studies and others, economic history has developed an increasingly self-conscious identity, not as a branch of applied economics but as a distinctive approach to the study of economic life.

Economic Restructuring: Geographic Aspects

Steven Pinch, University of Southampton, Southampton, UK

Abstract

Geographical studies of economic restructuring seek to explain spatial variations in economic development. The term 'economic restructuring' typically is used in a very general sense to indicate changes in the constituent parts of an economy. In many respects, it is a catch-all phrase, incorporating factors such as the changing nature of industrial sectors, corporate organization, management strategies, occupational structures, employment cultures, and working practices. However, the term 'restructuring' has also become associated with a series of geographical studies with distinctive perspectives on changing economies. Although a series of foci, rather than a single integrated approach, these perspectives share a common desire to understand the geographical complexities of economic restructuring without recourse to universal laws of economics that are assumed to work in all places at all times. Instead, economic behavior is seen as dependent upon the cultural norms and institutional practices manifest in particular places at specific points in the history of capitalist development. Restructuring studies focus upon the processes leading to restructuring, the mechanisms through which this restructuring is achieved, and the social consequences of these processes in terms of factors such as income distribution, occupational structures, the prevalence of unemployment, and the incidence of two-career households. Nevertheless, it is possible to group restructuring studies by a number of empirical foci and theoretical approaches: spatial divisions of labor, 'clusters,' globalization, services, knowledge-, network- and digital-based economies, and financialization.

Economic Restructuring: Common Underlying Themes of Geographic Studies

Geographical studies of economic restructuring seek to explain spatial variations in economic development. The approach taken in most of these studies differs from the neoclassical approach within economics, which attempts to discover universal principles or 'laws' of economic behavior that are relevant in all places at all times. In addition, the neoclassical approach places faith in the ability of market mechanisms within a capitalist economy to produce the most efficient allocation of resources in a way that is beneficial for all concerned. In marked contrast, the restructuring approach within geography sees economic behavior as highly dependent upon the social customs, cultural norms, institutional practices, and wider forces of capitalist development in operation at the time, and in the place, in which that behavior takes place. Furthermore, rather than a consensual outcome that is to the benefit of all concerned, the process of restructuring under capitalism typically is seen as a struggle between competing interest groups, leading to winners and losers. Geographical studies have therefore focused upon both the creative and destructive outcomes prompted by the continuous need for capitalist firms to generate profits (Storper and Walker, 1989).

The restructuring approach has generated a vast body of literature undertaken by geographers and other social scientists interested in geographical issues, including regional economists and urban sociologists. These studies have been prompted by recognition of the fact that geography is a central element in the restructuring process. Not only does restructuring vary from one place to another but, in addition, the differences between areas are used by various agents – governments, corporations, entrepreneurs, trade unions, and workers – to affect the outcome of the restructuring process itself. Geography, sometimes referred to as place or space, is, therefore, not just a reflection of these processes, it is a constituent part of the restructuring process itself. A good example of the role of space is when a corporation moves employment from an area in which labor costs are high to a low labor cost region, or from an area in which workers are resistant to new working practices to one in which they are more compliant.

Restructuring studies focus upon the processes leading to restructuring, the mechanisms through which this restructuring is achieved, and the social consequences of these processes in terms of factors such as income distribution, occupational structures, the prevalence of unemployment, and the incidence of two-career households. Nevertheless, it is possible to group restructuring studies by a number of empirical foci and theoretical approaches: spatial divisions of labor, 'clusters,' globalization, services, knowledge-, network-, and digital-based economies, and financialization.

These studies have in recent years broadly adopted a 'relational' view in which firms are conceptualized as having to coordinate with a range of other actors – workers, consumers, suppliers, regulators, and government agencies. This has led to a focus upon the role of various institutions (sets of rules) that affect these interrelationships and how these vary from place to place and between nations in what are termed 'varieties of capitalism' (Hall and Soskice, 2001; see also Peck and Theodore, 2007). Explicit use of the term 'restructuring' has fallen somewhat from favor in recent years but social scientists from a variety of disciplines continue to examine the spatial manifestations of the continual reconfiguration of the global economy.

Spatial Divisions of Labor

The first geographical approach to focus explicitly upon economic restructuring was spatial divisions of labor (Massey and Meegan, 1982; Massey, 1995). In essence, this concept

highlights the fact that throughout the first part of the twentieth century there was a shift in regional economic structures away from sectors toward functions. Within regional sectoral specialization, regions tended to specialize in all aspects of the production process of particular products, such as ships, cars, or textiles. Classic examples of regional sectoral specialization are the car manufacturing complex of Detroit or the once world-leading shipbuilding region of the Clyde in Scotland. However, following a shift toward regional functional specialization, in the second half of the twentieth century, regions tended to specialize in particular *stages* in the production process of a wide range of products. The spatial divisions of labor approach therefore argues that there is a tendency for different types of work to be undertaken in different places. Thus, corporate headquarters tend to be concentrated in large cities, design centers may be concentrated in high-technology clusters, while the routine assembly of products may be based in regions with low labor costs.

Spatial divisions of labor are manifest at other scales in addition to the region. At the city-wide scale, areas of manufacturing specialization are often termed 'industrial districts.' However, decentralization in the latter half of the twentieth century promoted functional specialization as new forms of work – and especially services – were introduced into suburban areas following the outmigration of people from inner cities. Spatial divisions of labor can also be seen at the international level. Hence, the advanced capitalist regions of North America, Europe, and Japan may be seen as global centers of corporate control, finance, product design, and innovation, while routine assembly jobs are undertaken in developing countries. However, research soon made it clear that there were few, if any, clear-cut geographical patterns, and the shift from sectors to functions was a tendency or trend rather than a specific outcome. Hence, different industrial sectors produced complex spatial divisions of labor, some of which overlapped and some of which did not.

The spatial division of labor approach attributed this geographical restructuring to the continual need of capitalist firms to enhance their profitability. There is much debate about the processes that led to low productivity and declining profitability in many industries in the second half of the twentieth century. One important influence was growing international competition from low-cost locations outside the Western world. Other factors were a lack of investment in new machinery and boring repetitive work (often associated with labor unrest). Another factor prompting the desire for economic restructuring in the early part of the 1980s was the influence of corporate raiders who issued junk bonds to gain control of major corporations. They then enhanced share values by asset stripping: putting new management into particular corporate divisions to enhance productivity through reductions in manpower and the introduction of new working practices, and then selling off the revitalized units. Prosecutions for insider dealing led to a progressive decline in the influence of the raiders, but gradually pensions funds and major financial institutions began to exert similar pressures on corporations to enhance productivity and profitability.

Geographical studies drew attention to processes that were particularly important in the late 1970s and early 1980s as companies began to respond to declining profitability at that time (Massey and Meegan, 1982). First, there was rationalization, a euphemism for the reduction of industrial capacity through factory closure or massive workforce cutbacks. Job losses and factory closures were especially pronounced in the older industrial areas of the United Kingdom, a pattern that was replicated in the United States, Europe, and Australia. Rationalization frequently was associated with spatial relocation as routine production functions were transferred to areas with low labor costs in developing countries. Not only were shop-floor workers made redundant, intermediate level white-collar workers were also laid off as corporations stripped out their elaborate managerial and administrative hierarchies (a process sometimes termed 'delayering' or 'downsizing'). Second, there was the process of investment and technical change. This involved capital investment in new machinery and equipment in an effort to increase productivity and the quality of products. This frequently was also associated with losses of employment. Third, there was the process of intensification: increases in labor productivity through managerial and organizational change.

Many of these changes were made to increase flexibility. Rather like restructuring, 'flexibility' is a word with a wide range of meanings, but in the context of economic restructuring it has taken on two further important associations. First, there is functional flexibility, the capacity of firms to extend the range of skills of their employees. This has often involved breaking down the barriers between different types of occupations. Second, there is numerical flexibility, the capacity of employers to alter the numbers of workers employed at any given time. This has involved a wide range of strategies including the increased use of temporary workers, part-time staff, casual employees, job sharing, shift working, flextime, annualized hours, and a wide range of innovative forms of job contract.

Two important factors underpin the need for flexibility. First, there is the ever-increasing pace of technological change, both of products and the means by which they are produced. Increased use of computerization has tended to break down some of the divisions between mechanical-based and electronic-based occupations. The other factor is increasing market volatility. Markets for certain mass-produced goods have become saturated while niche markets for specialized goods change rapidly. Producers therefore need to be able to adjust quickly and efficiently to variations in demand.

As with other aspects of industrial restructuring, the capacity to introduce flexibility shows complex geographical patterns and wide variations among regions. For example, in an attempt to escape from labor hostility to flexible working practices in older industrialized areas with a tradition of trade unionism, many companies have established new factories in areas that are free of such traditions. The location of US car plants outside of the traditional automobile assembly areas of Detroit and Michigan in recent decades, illustrates this trend. Restructuring has greatly affected the economic fortunes of different places, favoring some and devastating others.

One of the most quoted and influential aspects of the spatial divisions of labor approach is Massey's use of the geological metaphor. The economic geography of an area was likened to various phases or 'rounds' of investment in factories, plant, machinery, and labor. Each round leaves an imprint in the form of a layer or strata of development. Some of these

layers become eroded over the years by subsequent rounds of the restructuring process, but collectively they serve to shape the economic landscape. Critiques of the early spatial divisions of labor approach argued that it gave too much attention to the power of capital. A reformulated 'territorial division of labor' approach therefore attempts to take greater awareness of the capacity of workers to influence economic restructuring (Dunford, 2003) (*see* Local Economic Development).

Although the spatial divisions of labor approach recognized that women were often employed in routine assembly work, feminist perspectives have also highlighted the neglect of gender issues in many of these earlier studies. Earlier research focused upon work dominated by men – most notably the assembly of cars or high technology research and design work – even though women frequently were engaged in routine 'Fordist' assembly work. Studies tended to adopt the reserve army of labor theory to explain the position of women in the labor market (i.e., it assumed that they were a variable pool of workers taken on in times of high demand but rapidly laid off in times of recession). A number of flaws were soon apparent in this theory. First, it simply did not fit the facts; in the last quarter of the twentieth century, women were an ever-increasing proportion of the workforce rather than a 'reserve army.' Second, previous studies frequently ignored the socially embedded character of women's employment. The issue of skill illustrates this point well. For example, rather than being an innate attribute, women's so-called nimble-fingers, which supposedly make them suitable for low-paid routine assembly work in light industry, are now seen as socially ascribed. Subsequent work has shown how the combination of workplace, household, and community arrangements structure the job opportunities available to women (Hanson and Pratt, 1995). Gender issues are therefore a crucial element in processes of economic restructuring, as are many other socially ascribed human characteristics related to factors such as family status, ethnicity, disability, and age (*see* Gender and Feminist Studies in Geography).

Clusters

During the 1980s, there was intense interest in Japanese manufacturing practices, and this drew attention to a rather different structure to regional functional specialization. Because of the need for geographical proximity to their smaller component suppliers, who provided parts on a just-in-time basis (as required on the production line), large Japanese manufacturing firms began to perpetuate and enhance regional sectoral specialization. Indeed, there has emerged a second strand to the restructuring approach that argues that clustering of firms making the same products (known as regional agglomeration) was once again an important feature of the advanced economies. This approach has been prompted by the fact that some regions lead the world in the design and production of particular products. The classic case is Silicon Valley in California that leads the world in electronics and computer software (Saxanien, 1994). Other examples include racing car production in southern England, textiles in northern Italy, and machine tools from the Baden-Württemberg region of Germany. Rather than regional functional specialization, these examples suggest we are witnessing the resurgence of the industrial districts of an earlier age.

Following in the wake of the influential management strategist Michael Porter (1998), these districts are often referred to as 'clusters,' although the term is highly controversial (Martin and Sunley, 2003). Various other labels have been ascribed to such regions of economic activity by differing schools of thought including new industrial spaces (Scott, 1988), associational economies (Cooke and Morgan, 1999), and learning regions (Morgan, 1997). Although these approaches vary in emphasis, at root is a debate over the extent to which the processes observed by Alfred Marshall (1890) in industrial districts in nineteenth-century England (such as steel making in Sheffield) can be applied to contemporary economies. Marshall famously noted three basic sources of external economy, whereby small firms could gain by being in close proximity to each other: through access to pools of highly skilled labor; the availability of specialized and efficient local suppliers and services; and the benefits of a local 'industrial atmosphere' characterized by rapid dissemination of information, trust, innovation, and competition.

Updating these ideas, Scott (1988) explained clusters as the outcome of transaction costs – the costs of transforming inputs into products and services. Companies are faced with three choices in minimizing transaction costs. They can undertake activities internally (in-house) through some form of *hierarchy*, subcontract activities to external suppliers and contractors through the *market*, or adopt a halfway house and engage in collaborative activities with other companies through *networks*. Scott argued that changing economies of scale and scope were affecting transaction costs and leading to firms clustering together geographically in collaborative networks.

Economies of scale are factors that cause the average cost of a commodity to fall as the amount of output of the commodity increases. Internal economies of scale are those factors that apply to individual firms (irrespective of the size of the industry to which they belong). These internal economies usually ensure that the optimal scale of output is large in order to recoup the high costs of research, development, and specialized capital equipment. It is these factors that led in the past to the growth of large factories. This system has been termed Fordism after the system of mass production pioneered by Henry Ford in Detroit for the production of cars.

External economies of scale, in contrast, apply when the industry to which the firm belongs to (rather than the firm itself) is large. External economies include the development of specialized ancillary services, pools of skilled labor, and specialist component suppliers. If the output of the latter is large, this can reduce costs, thus potentially benefiting the industry as a whole. Economies of scope are factors that make it cheaper to produce a range of commodities (rather than to produce individual types of commodity in isolation) and again these economies of scope can be internal or external. Critics pointed out, however, that the transaction-cost approach is based on an economic logic that ignores historical factors (Sayer, 1989). This critique has led to an approach in restructuring studies that recognizes the social embeddedness of economic activities.

The concept of social embeddedness recognizes that all economic activity depends upon the social context in which it takes place (Granovetter, 1985). Economic systems are seen as the product of conventions applied by highly 'reflexive' (i.e., thinking and aware) human agents. All economic systems depend upon systems of meaning that are usually specific to particular places. In the context of regional development, this has led to a focus upon the institutional structures that encourage or inhibit economic activity. Work has therefore focused upon the cultural factors that generate a strong sense of common purpose, trust, and skill development amongst geographically clustered firms. This trust can be fostered by 'strong ties' based on regular and intense face-to-face contact, but this sort of close-knit networking can lead to rigidity in thinking, and there is also recognition that fleeting contacts with people from a large pool on nonoverlapping networks can bring workers into contact with a wider range of ideas (e.g., Storper and Venables, 2004).

Another critique of the focus upon agglomeration economies in cluster theory has come from evolutionary perspectives. A rapidly growing force within the discipline, evolutionary economic geography attempts to show how socioeconomic systems change over time, drawing inspiration with metaphors, and concepts from a variety of evolutionary sciences (Martin and Sunley, 2006). Hence the approach looks at how firms with superior capabilities tend to survive and how consequently their workers inherit capacities and routines of operation that they pass on in various ways to later generations. After analysis of US automotive and electronics clusters, Klepper (2010) argues that rather than being a manifestation of distinctive locality-based agglomeration effects, these clusters reflect such an evolutionary learning process resulting from new businesses spinning out from a few original firms whose initial location was largely the result of historical accident. Klepper (2010) argues that the new firm entrants in his clusters were largely indigenous spin-offs and that their superiority in terms of survival and profitability reflected their innate characteristics. However, as he also acknowledges, this raises the further issue of how were these superior capacities acquired; was it through the experiences gained by these new entrepreneurs in superior (or perhaps problematic) original firms in the locality? Further research is required in this area, and it is likely that both evolutionary and agglomerations effects work in combination in clusters.

Globalization

Those who are skeptical about the importance of these 'new industrial spaces' have pointed to the overwhelming power of the forces of globalization, and this forms another major focus within studies of economic restructuring in what has been termed the Global Production Network approach (Dicken, 2011). Globalization is – like most aspects of restructuring – a highly controversial and much disputed concept. The term is usually associated with the growing importance of multinational (or transnational) companies that operate in more than one country. However, large corporations such as Ford have long manufactured outside of their parent nation, producing goods for consumption in distant markets. Globalization therefore refers to a more recent process in which the operations of transnational corporations (TNCs), both in the spheres of production and distribution, are increasingly integrated on a global scale. Thus, products typically incorporate components made in diverse locations throughout the world. Furthermore, while the appearance of products such as cars may be tailored to meet the demands of particular local market conditions, this diversity is underpinned by many common elements (such as the floorpans and engines in the example of automobiles) to reduce production costs. The Global Production Network approach attempts to conceptualize these production systems as a complex web and not simply a linear chain. Studies of TNCs have focused upon how they manage to cope with the variety of institutional rules, regulations, and cultures to be found in differing nations and trading blocks, highlighting the fact that strategies are highly diverse (Wrigley et al., 2005). For example, an important strategy by US corporations in response to increasing competition from Asian corporations has been the development of 'modular production' (Sturgeon, 2002). This involves formalizing, through various standards and protocols, all the knowledge about products into particular stages of the production process, thereby enabling components to be outsourced throughout the world. Influential work has also focused upon global professional services firms showing how they adapt to different institutional contexts around the world (Faulconbridge, 2008). Globalization is also associated with the global spread of Western values of materialism and consumerism (*see* Globalization: Geographical Aspects).

Globalization has had a crucial effect upon economic restructuring. In particular, it has led to the emergence of so-called world cities (or global cities) – command centers of the new world economy that house the headquarters of the major corporations and the financial system (Sassen, 2001). Examples include New York, Los Angeles, London, Paris, and Tokyo. The occupational structures of global industries are such that these cities tend to be characterized by extremes of affluence and poverty. While few cities can claim true global status, there is a sense in which all urban centers are now global, for they are all affected by events outside their boundaries and they are all engaged in a fierce competition to attract mobile capital investment into their districts. Those who are skeptical of the clustering thesis argue that it is the elaborate structures of global corporate hierarchies that shape economies rather than industrial clusters in specific regions.

One approach to reconciling the conflict between the globalization and 'regionalist' schools of thought is through the concept of neo-Marshallian nodes (Amin and Thrift, 1992). This concept draws attention to the importance of geographical clusters of small firms but at the same time recognizes that they are frequently dependent upon the activities of major corporations located throughout the world (*see* Industrial Geography). Another influential article on the issue of local agglomerations of economic activity argued that clusters were advantageous for the circulation of 'buzz,' tacit uncodifiable knowledge, whereas 'global pipelines' were more suited to the dissemination of codifable knowledge (Bathelt et al., 2004).

However, some have argued that there cannot be any such simple equation of types of knowledge with geographical scale (Amin and Cohendet, 2004).

Services

Geographic studies of economic restructuring also focus upon the growth of services (Bryson et al., 2003) (*see* Service Economy, Geography of). Although services are notoriously difficult to define, a common theme is economic activity that does not involve the material transformation of a physical product. However services are defined, there is little doubt that service activity is dominant in terms of total employment and is on the increase in Western societies. Growth has been especially pronounced in financial and business services (sometime known as KIBS – knowledge intensive business services), retailing, leisure, and entertainment industries. Growth in services has tended to concentrate outside the traditional manufacturing centers of the Western economies (e.g., in the Sunbelt of the United States and in the South East of the United Kingdom). However, new telecommunications systems are enabling back-office activity (i.e., relatively routine service activity) to be decentralized away from areas of rapid service growth into older industrial areas and to call centers in the Asian subcontinent.

The restructuring of services has had profound effects upon the social structure of economies. In particular, it has led to social polarization with increases in both the affluent and the less well off. Whereas the declining traditional heavy manufacturing industries had substantial proportions of blue-collar, relatively well-paid, middle-income jobs, services tend to be associated with both relatively high-paying and low-paying jobs. Closely connected with the growth of services has been the increasing numbers of women in the workforce. Whereas men were employed in most of the relatively well-paid jobs in manufacturing, many of the new relatively low-paid service jobs (but also some of the well-paid service jobs) are held by women.

An important element of service growth has been the 'cultural' (or 'creative') industries such as advertising, design, entertainment, media, and publishing. Although highly diverse in character, these industries involve cultural products such as books, films, plays, advertisements, video games, and fashion clothes that are imbued with aesthetic and symbolic elements. The growth of creative industries has been closely linked with another worldwide trend in economic restructuring in recent years – the growth of culturally driven urban regeneration (Cooke and Lazzeretti, 2008). This trend involves not only the provision of concert halls, theaters, art galleries, and museums for the consumption of culture but also local creative quarters within cities for its production. The markets for these cultural products are typified by rapid changes in technology and fashion, and in response the cultural industries are often concentrated in close proximity in cities. Here the workers in these industries can utilize informal social networks and face-to-face contacts to pick the latest 'buzz' on the streets about changing fashions.

Knowledge-, Network-, and Digital-Based Economies

Another important strand of economic restructuring work by geographers has focused around knowledge economies (*see* Information Society, Geography of). This role of knowledge is reflected in the ever-increasing pace of technological change and the rapidity of changes in consumer fashions and styles. This means that, rather than competing by providing goods and services at the least cost, many firms increasingly compete on the basis of factors such as quality, performance, style, and design. Rapid developments in the sphere of telecommunications – the Internet, e-mail, teleconferencing, and various types of specialist computer networks – mean that knowledge can be disseminated much more quickly throughout corporate hierarchies or networks of collaborating firms. Central to these developments are new communications channels based around satellites and fiber optics that permit the exchange of greater and more complex amounts of information much more quickly over longer distances. The term 'network society' (Castells, 2009) has been coined to encapsulate all these various technologies that permit new socioeconomic and cultural practices such as social networking, online shopping, gambling, and open-source programing.

Despite much speculation, the full impact of the network society on economic restructuring is still unfolding. However, many developments are already evident: the emergence of mammoth digital companies; the rapid growth of on line retailing and the associated near disappearance of many city center retailers (including most notably music and book stores); illegal downloading that has challenged the business models of the popular music and movie industries; and new technologies that facilitate ever-faster responses to changing market demands with new products. The network society has also facilitated globalization and ever-increasing distances between the various elements in the production chain. In addition, it facilitates telecommuting by linking people into global information networks and enabling them to work in their own homes. While some claim new technologies will result in the dissolution of city life, paradoxically, cities remain highly prized as sites of innovation and creativity. The reason for this is (as noted before in services) that creativity in knowledge-based industries is fostered by having dense networks of people in close physical contact in places where trust and reciprocity can facilitate learning. Furthermore, much of the expensive infrastructure needed in the digital economy is heavily concentrated in urban areas.

Financialization

The specter looming over any discussion of economic restructuring is of course the current global recession following in the wake of the 2007–08 'credit crunch.' This crisis has been attributed to a process called 'financialization,' generally understood to indicate the growing dominance of finance capital markets on economic and social life (Pike and Pollard, 2010). However, compared with other aspects of economic restructuring this profoundly important process so far has

received relatively little attention from geographers (Pike and Pollard, 2010). In part, this neglect derives from the complex nature of financialization, since it involves a diverse set of financial initiatives – commonly known as derivatives – that attempt to convert virtually all types of economic transaction into 'packages' or 'bundles' (i.e., units of value that can be traded like a form of currency). The broad contours of the crisis engendered by this process have received enormous publicity and seem to be generally understood. As one example, US banks attempted to spread the risk of subprime mortgages lent to high-risk, low-income groups by using various financial instruments known as collateralized debt offerings or structured investment vehicles that were then traded to financial institutions throughout the world. The inability, or unwillingness, of those in the financial system to appreciate the risks involved in such instruments led to bad debts, risk aversion, a lack of liquidity in financial markets, state bailouts for banks, sovereign debt crises, fiscal austerity, and the stagnation of global production. Certainly, much of the process of financialization is hidden in complex corporate structures, opaque balance sheets, tax havens, and ever more complex financial schemes that are protected by armies of financial intermediaries who have enormous legal power and political clout. Understanding how this global financial system came into being, how in the wake of such disfunctionality it is able to reproduce itself, and, most importantly, how it might be regulated for the common good, are crucial tasks for future studies of economic restructuring (Dymski, 2010).

Overview

Rather than a single integrated approach, geographical studies of 'economic restructuring' represent a series of highly interconnected foci: on spatial divisions of labor, clusters, globalization, services, knowledge-, network-, and digital-based economies, and financialization. Nevertheless, these studies share a common desire to understand the many complexities of economic restructuring without recourse to simple laws of economics that are assumed to work in all places at all times. In addition, they are all committed to unraveling the crucial role of geography as a constitutive element of restructuring processes. Although many generalizations have been possible, the geographical manifestation of economic restructuring shows many complex, ever changing, and cross-cutting patterns. Although somewhat distinct from the approaches typically utilized by economists, restructuring studies have attracted considerable interest from a wide range of scholars in related disciplines such as urban studies, planning, sociology, and cultural theory. Studies of economic restructuring have forged especially strong linkages with economic sociology and political economy (*see* Economic Geography).

Abstract

Economic sociology is the study of how the material conditions of life are produced and reproduced through social processes. The field of economic sociology can be separated into the sociology of markets and the sociology of consumption. The sociology of markets views markets as socially constructed arenas where repeated exchanges occur between buyers and sellers under a set of formal and informal rules governing relations between competitors, suppliers, and customers. Markets are dependent on governments, laws, and cultural understandings that support market activity. There are four bodies of work that provide different views on the mechanisms by which markets are organized: networks, institutions, political economy, and the study of market devices and the performativity of economic ideas. The sociology of consumption situates consumption in the problem of what consuming things means to people. One core idea is that consumption is about how people constitute their lifestyles. Lifestyles can be constructed in emulation of other groups or instead by competition between social groups for status. Another aspect of consumption is how morals and meanings affect what goods can be bought and sold. Scholars have explored why some products can and cannot be commoditized and how that has evolved over time.

Introduction

Over the past 30 years, economic sociology has erupted into a vibrant and visible subfield as sociologists increasingly apply social theories to study the economy. Scholars have challenged the separation of economy and society to show how social arrangements constrain, enable, complement, and constitute economic phenomena. Building upon Granovetter's (1985) admonition that economic life is embedded in social life, economic sociologists have identified social mechanisms – such as networks, institutions, and morality – that provide the contexts, conduits, and categories integral to economic action. This article offers a definition of the field, suggests its main branches, and gives a flavor to how sociologists have tried to explain various economic phenomena.

Economic sociology is the study of how the production and consumption that define material life depends on social processes for their structure and dynamics. Practically, the field can be divided into two parts: the sociology of markets and the sociology of consumption. The sociology of markets is concerned with how market participants and stakeholders solve the problems of production and exchange. We consider four of economic sociology's most generative approaches to the sociology of markets – network analysis, institutionalism, political economy, and creation of market devices including scholarship that focuses on how economic theory is performed to create markets. The sociology of consumption focuses on what goods and services mean to consumers and how they use them as a means to distinguish themselves from others by constituting lifestyles. The authors discuss how scholars have used culture, meaning, status, and morality as analytic tools to distinguish the ways in which consumers accept or reject new products.

Sociology of Markets

Sociologists define markets as socially constructed arenas where repeated exchanges occur between buyers and sellers under a set of formal rules and informal understandings that govern relations among competitors, suppliers, and customers. These rules and understandings guide interactions, facilitate trade, define what products are produced, sometimes constitute the products themselves, and provide stability for buyers, sellers, and producers. In modern capitalism, markets also depend on governments, laws, and larger cultural understandings to operate (Fligstein, 2001).

One way to conceive of this is that participants in a market form reproducible role structures – that is, sets of recognizable participants who occupy certain positions (such as incumbent market leader or upstart challenger) and interact routinely over time (White, 2002). This view opens up the questions at the crux of the sociology of markets. What general problems must be solved for markets to emerge? How do role structures stabilize? How do markets evolve? How do they die or transform into other markets? What is the role of states in the construction and maintenance of markets? The various sociological theories the authors discuss propose alternative ways to think about how to answer these questions.

Markets qua self-reproducing role structures can emerge without state intervention. Before the modern era, extensive relationships between market actors made this possible – relationships that often depended on common kinship, ethnicity, or religion (White, 2002). These commonalities created trust, allowed actors to monitor one another, and offered ways to settle grievances (Granovetter, 1985). Informal rules and local cultures emerge within industries regarding the legitimate way to organize a firm, compete with other firms, and buy and sell products.

While neoclassical economics claims that price is an ever-emergent phenomena guided by the 'invisible' hand of the market, economic sociologists argue that price is the result of social relationships and shared understandings among market participants. Producers will pursue a number of social strategies such as product differentiation, collusion, and co-optation rather than take part in destabilizing price competition (Fligstein, 2001; White, 2002). Producers will mimic the

organizational forms and business models of legitimate firms in the field in attempts to win the support of customers and resource providers (DiMaggio and Powell, 1983). These mimetic pressures will often lead to the widespread acceptance of certain heuristics and models for economic behavior. Performativity theory suggests that market participants, often trained in the world's best business schools, import formal economic theories and models into their local market cultures (Callon, 1998). In industries where these models have gained widespread support market activists perform theory, turning the discipline of economics into 'an engine, not a camera' (Mackenzie, 2006).

For stable markets to emerge and distribute goods successfully, market actors must solve a range of problems. Their solutions produce the conditions that make a particular product market, industry, national economy, or regional economy distinctive. For example, in the early stage of a market's development, a product's qualities need to be defined. Governments, firms, and customers have input into the question of what count as safe food products, useful telecommunications standards, or tradable financial securities. Firms must also develop the competency and capacity to produce these goods. They need to be able to trust their suppliers, employees, and customers in order to secure inputs, labor, and capital. Thus, networks of social relationships help firms stabilize their environments and guarantee access to scarce resources. Firms must be able to forecast the activities and responses of their competitors in order to position themselves in the ongoing struggle for market share, and therefore need access to information on their competitors. Finally, by responding to directives from the government and trying to co-opt government agencies, firms can also secure their futures.

Theoretical Approaches: Network Analysis, Institutional Theory, Political Economy, and Market Devices and Performativity

The sociology of markets draws heavily on four theoretical approaches to offer concrete guidance about how to study market processes: network analysis, institutional theory in organizational studies, political economy and the literature on market devices, and ideas about the performativity of economic ideas drawn from the social studies of science. These four schools of thought offer different conceptual tools to make sense of what happens in markets. At the same time, there are overlaps in what each school stresses. For example, institutional theory and political economy both emphasize the state's role in constructing markets. Network analysis and institutional theory explore how the networks that constitute social structures transmit market information, define standard operating procedures, and generate trust. Market devices and the use of economics as a way to structure markets dovetail nicely with institutional theory's emphasis on the social constructedness of markets. Finally, governments frequently provide legitimation and even law and regulation for particularly market devices to evolve and be implemented.

Network analysis is a metaphor, a set of techniques to display data, and a way of studying the social mechanisms by which key market problems get resolved. If the sociology of markets' key insight is that market actors are embedded in social relationships that define who they are and what they do, then network analysis is the starting point for mapping those relationships (Powell and Smith-Doerr, 2005). Formal network-analysis techniques have demonstrated how the relationships among actors help explain what they will do: whom they will hire, and with whom they will trade goods and exchange capital. Networks also serve as conduits for information, operate to mitigate problems of trust, and control resource dependencies (Podolny, 2001). It is now firmly established that the connections among actors can affect prices, increase the probability that well-connected firms will survive, and help market participants compete and find customers and suppliers (Uzzi, 1996, 1997).

Institutional theory emphasizes informal understandings and cognitive frames that shape the social structure of markets. Institutional theorists often conceptualize markets as fields where firms watch one another, imitate one another, and build niches to reproduce their positions (DiMaggio and Powell, 1983). The observant and reflexive character of firm behavior can often mitigate competition and stabilize markets. Yet institutions are rarely fully settled or taken for granted. Even stable institutions are under ongoing contestation as various stakeholders such as firms, trade associations, unions, academic or professional experts, and community organizations construct resonant frames and mobilize resources to change state laws, reconstruct product categories, and shape industry 'best practices.'

Institutional theory also stresses how the formal laws, regulations, and actions of states and courts have profound effects on market structure (Dobbin, 1994). From this perspective, states and markets are joined at the hip. Moreover, firms can appeal to states for help. When incumbent firms successfully shape the rules governing their industry, they can reproduce their leading positions over time. Institutional theory stresses not only how states set rules and enforce sanctions, but also how they define what types of products are appropriate for exchange. Scholars with an institutionalist perspective also examine how the internal dynamics of states affect the way they intervene in markets. The structure of courts, ministries, and regulatory agencies, as well as struggles among parties and political factions, all affect state intervention.

Economic sociologists recognize the important role that the state plays in supporting and sanctioning market institutions (Crouch and Streeck, 1997; Hall and Soskice, 2001). States grant property rights, enforce contracts, regulate collaboration and competition, and establish standardized rules of exchange. Scholars have shown how state building and market building are coevolutionary processes and that political stability is a precondition for market growth (Crouch and Streeck, 1997). State prohibition of certain goods such as drugs, sex, and human cadavers relegate buyers and sellers of these products to the unstable and resource-poor black market (Fourcade and Healy, 2007; Beckert and Wehinger, 2013).

The state has the ability to use policy to shape both the competitive landscapes of industries and organizational forms of firms. Fligstein (1990) shows how in the late nineteenth century the American government used antitrust laws to foster competition and break up cartels. Similarly,

Dobbin (1994) shows how government policy in the early twentieth century played a critical role in shaping the organizational forms of railroad companies.

Political economy has pioneered thinking about the linkages between states, law, and markets and the historical emergence of systems of governance. The political economy literature on 'comparative capitalisms' – the comparative study of capitalist arrangements and their effects on various outcomes, including economic development – is a fundamental part of the sociology of markets (Hall and Soskice, 2001). This literature has revealed that the relationships among governments, workers, and capitalists have varied dramatically over time and geography, and that economic trajectories are often culturally and nationally specific. Markets are social and political constructions reflecting a country's culture, its history of class relations, and the various interventions its governments have carried out through history (Fligstein, 2001). In this view, each national system of capitalism forms an integrated whole: an enmeshed set of institutions such as systems of labor relations, modes of capital allocation and corporate control via securities markets and bank lending, systems of education and training, tax systems, and state involvement and ownership in key industries.

The political economy literature has been the most forthright about trying to understand which systems produce the most sustained economic growth. Scholars have documented that different national systems of capitalism exist and have debated how to fit them into categories, such as on the basis of national protectionism, levels of state intervention, and modes of capital allocation to firms (Crouch and Streeck, 1997). Yet, beginning with the collapse of communism in the late 1980s, a whole series of studies began to appear asserting that differences among national capitalist systems would soon disappear. These studies predicted that as global capitalism spread and barriers to international trade and capital flows crumbled, production and consumption would shift to those countries with the most efficient market institutions, bringing governments to their knees and forcing rapid convergence to a generic liberal model of capitalism (Strange, 1998). However, this prediction proved false. Research suggests that national systems of capitalism are resilient, even in the face of political and economic crises. This has led other scholars to conclude that key features of these systems must enable firms, states, and workers to adapt efficiently to new challenges (Hall and Soskice, 2001).

Scholars have also sought to understand economic transformation in the postsocialist world and other developing economies. They have documented the collapse of institutions in Eastern Europe and Russia and have analyzed the features of the systems that have taken their place. China has also been the focus of sustained study (Nee and Opper, 2012). The main issues in this literature involve the role of the state in the market. Research shows that states with disorganized bureaucracies and poorly paid, incompetent bureaucrats are more prone to rent-seeking than those with educated and better paid staff. Scholars also agree that defining property rights clearly and assuring the rule of law are important to development. But establishing such institutions is difficult to do from above; they usually arise dynamically from the demands of firms and citizens. Also controversial is the relationship between economic development and state investment in particular firms and industries. States have done this successfully in some cases, but failed miserably and wasted scarce resources in others (Evans, 1995).

The literature on market devices focuses on a problem that neither network analysis nor political economy is very good at treating. For markets actually to work, products need to be created, evaluated, and priced. The institutions that do this are 'market devices,' widely accepted rules of thumb, tools, technologies, and theories that help actors value goods, weigh options, and follow corresponding strategies in the marketplace (Biggart and Beamish, 2003). The literature includes at least two approaches to thinking about market devices. One originates with the idea that we need conventions to make judgments of price and quality simpler. For example, if a bank wants to loan money, it must judge each customer's creditworthiness. Over time, ratings agencies have developed different quantitative yardsticks that allow banks to judge the riskiness of loans. In commercial lending, these ratings involve putting letters from AAA to D on corporate bonds (Carruthers and Stinchcombe, 1999).

The problem of price setting is a very general one with far-reaching implications for firm behavior. Deciding how much to pay someone, whether or not a bottle of wine is worth $50, and how to make such judgments require a whole social infrastructure (Karpik, 2010). Many of these comparisons involve rankings and other quantitative indices. Once in place, such market devices can take on a life of their own. Actors in markets use them not just to decide what to buy or sell, but to measure themselves and their performance against others. Rankings can push firms to reevaluate their strategies and tactics in order to improve their standing.

This brings us to a second way in which market devices get constructed: via the performativity of economics (Callon, 1998). One area of work that has been particularly productive has examined how principles and quantitative models from economics can structure financial markets. For example, there is a body of theory in economics that discusses how different types of auctions work. Not surprisingly, sellers deploy this knowledge to auction hard-to-value objects. Thus, the science of economics actually makes the market for such objects possible. In the case of futures contracts traded on exchanges, derivatives traders' use of the Black–Scholes–Merton (BSM) theory for pricing derivatives actually caused prices to approach the values that BSM predicted (MacKenzie and Millo, 2003). Scholars term the implementation of economic ideas to structure markets 'performativity.' This label implies that one self-consciously takes an idea and puts it into practice: literally, one performs it.

Financialization and Globalization

One empirical arena to view the analytic power of the perspectives that make up the sociology of markets is the study of financialization and globalization. Financialization is a set of related phenomena that reveal "the increasing role of financial motives, financial markets, financial instruments, financial actors, and financial institutions in the operations of domestic and international economies" (Epstein, 2005; p. 3). It

comprises the growing dominance of finance tools in the management of firms, the ability of financial markets to dictate what firms and governments do, and the growth and importance of the international financial system in the distribution of capital around the world (Krippner, 2011; Davis, 2009). As such, making sense of it requires the use of all the perspectives just discussed.

The growing dominance of finance tools corresponds with the rise since the 1980s of the shareholder-value view of the firm, particularly in the United States (Useem, 1993). These tools allow managers who view the firm through the lens of the balance sheet, such as chief financial officers (CFOs), to maximize shareholder value (Zorn, 2004). The basic idea of the shareholder-value view is that firms exist to provide returns to shareholders. Shareholders of publicly held corporations care primarily about two metrics: (1) share price and (2) the ratio of profits to assets. With this in mind, managers use a range of tools to increase these metrics, including financial engineering of balance sheets, outsourcing, downsizing, investing in technology, cutting salaries and benefits, and increasing the working hours of the employees who remain. Upper level managers frequently receive shares and bonuses for meeting financial targets.

The rise of the shareholder-value view, and the concomitant ascendance in power of finance-oriented managers (such as CFOs) originated in firms' changing relationship with the financial markets. Scholars have documented that during the 1980s' merger movement, institutional investors pushed management teams to increase their profitability. When managers resisted, their firms became takeover targets. Since then, the relationship between the financial markets and the largest corporations has been symbiotic (Useem, 1993; Davis, 2009).

Corporations' reorientation toward shareholder value and the financial markets is not the only manifestation of financialization, however. Financial markets themselves have grown enormously and become integrated globally (Knorr Cetina and Bruegger, 2002; Leyshon and Thrift, 2007). Net transnational flows of bonds, bank capital, investment capital, and derivatives each dwarf the revenues of major corporations and even many states. The creation of complex financial products and the globalization of finance have produced an important new literature in economic sociology. Scholars focusing on instruments tend to be grounded theoretically in science and technology studies and the social studies of science in general, in actor–network theory, and in a strong appreciation for the technical details of the machines that make markets work (MacKenzie, 2006; Knorr Cetina and Bruegger, 2002; Callon, 1998).

Scholars have struggled for years to understand how national systems of governance respond to the pressures produced by financialization and globalization. Many consider it inevitable that global economic pressures, including the whim of sovereign-bond markets, will limit national governments' degrees of freedom. This will force governments not only to deregulate product markets but to cut back on welfare expenditures and labor protections. However, evidence for this 'race-to-the-bottom' proposition is mixed at best (Strange, 1998). While there have been some changes in the way that governments regulate, tax, and spend in the past two decades, there is no consistent trajectory across countries. Many of the national capitalisms have changed in response to these pressures, but mostly by modifying their existing national models (Hall and Soskice, 2001).

Sociology of Consumption

The sociology of consumption is focused on what goods and services mean to people (Zukin and Maguirre, 2004). Consumption is most frequently studied by focusing on how what one consumes is a statement about lifestyle. Studies focus on how baskets of goods are expressions of who one is and how one wants others to think of him or her (Bourdieu, 1984). Most scholars emphasize that lifestyle is an ongoing construction, one that can turn into an escalating arms' war as people compete over important high-status goods (Schor, 1999). One important strand of this work focuses on how advertisers push this race along by promoting the consumption of goods and services to people in order to get them to consume more and thus, obtain more social status (Slater, 1997). A second focus in research is how goods are constructed by cultural categories, categories that often imply something about societal conceptions of morality. So, for example, the boundaries between things one can sell and cannot sell imply the moral edge of society. One focus of such studies is how some products, which were previously immoral, come to be seen as moral.

Consumption is often an attempt to secure social status and produce a lifestyle (Bourdieu, 1984; Elias, 2000). Historical sociologists have documented how this process occurred in early modern Europe, when the newly rich bourgeoisie tried to mimic the nobility. This led the nobility to shift the markers of high social status continuously in order to retain their edge over the rising bourgeoisie. Elias (2000) shows that this lifestyle competition eventually came to include both the middle and working classes. More recent work has tried to view lifestyle as not just competition whereby those at each level of society try to emulate those above them but one where lifestyle can be oppositional. The strongest proponent of this view is Bourdieu (1984), who shows that those lower down the income and education hierarchy find themselves as losers in a process where money can buy status, and as such, decide to consume and value different things.

In the past 20 years, scholars have emphasized how such status hierarchies remain dynamic and continuously shifting. One important place to observe such processes is in the race for positional goods like cars, good schools, fashion, and houses. As income inequality has increased in America, the price of positional goods has increased. In order to keep up, working-class Americans have taken on debt to finance their consumption and 'keep up.' Going into debt to keep up with the Joneses, or leveraging home equity to finance one's children's education, is viewed as a reasonable life decision (Schor, 1999).

The question of how consumers think about goods and services has produced much interesting work on household budgeting, gifts, and the line between which products are considered moral to consume and which things should not be

for sale. Zelizer (1997) has shown that households do not view their income as fungible (i.e., a dollar spent on one thing can be just as easily spent on another) but instead view income as pots of money dedicated to particular categories of consumption. So, frequently things like inheritances are kept as a lump sum of money put to a family need like a house or an education.

The study of the line between which products are morally acceptable to buy and sell in markets and which ones are not has been a productive field of study (Fourcade, 2011; Fourcade and Healy, 2007). One important question is how do such boundaries change over time as new problems come up to be solved and therefore change the moral calculus applied to a particular 'thing.' Life insurance offers examples of the marketization of new goods. When life insurance was first introduced, people found it morally repugnant. The idea of paying for such insurance seemed like a macabre commoditization of death that verged on gambling. But over the course of the nineteenth century, life insurance became viewed by middle class families as a prudent way to provide for one's kin in the event the main bread winner passed away (Zelizer, 1979).

More recently, during the 1980s and 1990s, selling one's life insurance policy to a third party went from being widely considered morally abhorrent – because it gave someone else an incentive to wish for one's early death – to being the basis for a new market in 'viaticals.' The AIDS epidemic moved forward this transformation in markets: as AIDS patients faced rising health care bills and poverty, they sought to sell their own life insurance policies. Here, the moral discourse in favor of a dignified death came to trump the moral discourse against betting on death, producing a new market (Quinn, 2008).

Conclusions

This panoramic review of economic sociology has touched on many of the major themes in this growing literature. Economic sociology has laid down a tapestry of compelling theoretical perspectives and empirical work. They have been used productively to understand the formation of new markets and the role of states in creating markets. They have pushed scholars to consider the social structuring of markets and the meanings that have come to organize and constitute the existence of new markets. The sociology of consumption has provided a theoretical and empirical basis to consider why people consume. It has pushed scholars to think about how culture and morality frame such decisions and structure the existence of new markets.

Economic sociology has added richness to the ability to understand the behavior of individuals, households, firms, markets, and national systems of capitalism. At the micro-level, it shows how ongoing interpersonal relationships play an important role structuring various economic processes. At the meso-level, it describes how established industries rely on institutional architecture, formal and informal rule systems, to make life more predictable and mediate problems related to production, competition, valuation, and exchange. At the macro-level, it reveals how historical differences in state laws and national cultures foster different forms of capitalism with varying conceptions of efficiency.

Abstract

This article outlines the economic transformation from central planning to the market system that socialist countries embarked upon at the end of the twentieth century. Over 30 countries, comprising Central and Eastern European countries, republics of the former Soviet Union, China, and Vietnam, undertook the transition from plan to market and from socialism to capitalism. Key elements of the transformation are discussed, namely, theories and paradigms, central planning and initial conditions, reforms and economic policies, institutions, performance and outcomes, and, finally, lessons and an assessment of this unique social science experiment.

A new subbranch of economics emerged at the end of the twentieth century. It arose from the collapse of the Soviet socialist system (and the earlier reforms in China and Vietnam) and the subsequent transformation from a centrally planned economy to a market economy. It is known as transition economics where transition is defined as the social, political, and economic transformation from a command system characterized by state ownership, collective action and central planning to a market system characterized by decentralized decision-making arrangements and private sector market transactions. Although it overlaps with other branches of economics, most notably Comparative Economic Systems and Development Economics, the study of transition economics was sufficiently distinct to warrant its own subbranch within the discipline of economics. This short article will focus on the economic transformation dimension of transition economics, and, in particular, examine a number of key elements, namely paradigms, central planning and initial conditions, reforms and economic policies, institutional change, performance and outcomes, and, finally, lessons of the economic transformation from plan to market.

Leaving aside the debate over whether 'transition' or 'transformation' was the most appropriate term, the change from central planning to the market economy and from socialism to capitalism has been described as one of the most important economic, social, and political experiments of modern times. Indeed, many view the transition from plan to market as one of the two most important economic events of the last century, the other being the Great Depression of the 1930s. Just as the causes, consequences and lessons of the Great Depression are still matters for ongoing discussion and research (and particularly since the 2008/09 Great Recession), the transformation experience from plan to market is likely to attract debate and controversy for decades to come. At the peak of the socialist system, one-third of the world's population lived in socialist countries. However, within a short space of time these countries had abandoned state socialism and embraced the capitalist system with its market economy. Although the transformation was remarkably peaceful, it has proved to be both costly and painful for many countries, regions, and sections of society. Many citizens in transition economies (TEs) witnessed an erosion of living standards and public services. For others, it has been a time of extraordinary opportunities, in both political and financial terms.

Why study the economic transformation from central planning to market economy? For one, it gives us a rare insight into the alternative economic systems, namely the central plan and the market. Two, we get a better understanding of what is involved in systemic and large-scale institutional change. Three, it offers an insight into policy reform and the politics of economic reform. Four, it allows for a timely reappraisal of some key economic debates such as the Washington Consensus, the debate over markets versus states, the importance of institutions and contracting, and the role of privatization and small and medium-sized enterprise (SME) development. Five, concepts and economic ideas studied in transition such as state capture and corruption, asset stripping and tunneling, the soft budget constraint and ratcheting, mass privatization and dual-track price liberalization, shock therapy, and incrementalism have relevance far beyond economic transformation and transition countries. Finally, it is now generally accepted that the economics profession has a great deal to learn from this transformation experience and that these 'lessons' influence and, over time, improve our understanding of economic systems, capitalist economies, (new) comparative economics, and mainstream economics, and provide a valuable insight into other areas of economics (Djankov et al., 2003; Ellman, 2013).

Theories and Paradigms

Strictly speaking, there is no 'theory' of transformation from a centrally planned system to a market system. In the late 1980s, when change was imminent in the Eastern bloc countries (and was already underway in the East Asian countries of China and Vietnam) there was no theory of transformation from plan to market that policymakers and supporters of reform could adopt. What evolved over time are two different approaches to understanding the transformation process from a centrally planned economy to a market-based economy. The conventional paradigm is the Washington Consensus approach to economic transition and the alternative paradigm is the institutional-evolutionary approach (see Roland, 2000; Turley

and Luke, 2010). The Washington Consensus approach dominated in the early years of transition and had the support of the international financial institutions (IFIs). This orthodox or standard vision, especially popular in the Anglo-Saxon world – seen by many as an expression of the neoclassical mainstream – views transformation as a reform process emphasizing the universality of the laws of the market and the undoubted economy-wide efficiency gains accruing from the standard policy prescriptions of the trinity of liberalization, stabilization, and privatization. This blueprint for transformation, based on the spontaneity of markets and private enterprise, traditional neoclassical price theory and Walrasian general equilibrium theory, promoted the primacy of policy reforms and economic fundamentals and the replication or transplantation of international best-practice institutions of the West to the socialist countries of the time. Although the Washington Consensus emerged from a different set of conditions, it argued that these one-size-fits-all market-oriented reforms are appropriate to any setting, socialist or otherwise. A knowledge or experience of the state socialist system and the centrally planned economy is not required. Regional studies and area specialists emphasizing the importance of historical, cultural, and socioeconomic factors were dismissed. Instead, liberal economic reform strategies are implemented along a scorched-earth approach, with textbook reforms being designed by technocrats as the agents of social change and introduced as rapidly and comprehensively as possible in view of the reform complementarities that exist. Not surprisingly, in terms of the speed of the radical reforms, this approach is often referred to as the 'big bang' or 'shock therapy' view of transition. This also applies to the economic role of the state where what is required is a depoliticization of the economy, a break of the nexus between government and business, and a dismantling of the state, or, according to critics of the Washington Consensus approach, in the extreme case of neoliberal market fundamentalism, state desertion.

The institutional-evolutionary paradigm viewed transformation as a large-scale institutional change where the focus is on the institutional underpinnings of capitalism appropriate to the specific conditions of each country and in accordance with the initial conditions at the outset of transition. Following in the traditions of Schumpeter and others, this approach is inspired more recently by evolutionary theory, institutions, and the contribution of new institutional economics. It is critical of the revolutionary vision of transition and, instead, views transformation as an evolutionary process involving systemic change in the face of great uncertainty and complexity, based on contracting, noncooperative game theory in modern microeconomics and the second-best theory. Here, the focus is on the gradual development of the institutional supports or arrangements for a market economy, accepting the dangers of institutional voids and that not all existing or inherited institutions, organizational forms or social capital are redundant. Transitional second-best institutions and the preservation of social capital can be both worthwhile and necessary in order to prevent further economic disruption. The institutional-evolutionary perspective is a bottom-up view focusing on the institutional infrastructure of market economies, the importance of social norms and the organic development of the private sector. Markets and economic agents do not exist in a vacuum but in an institutional framework that facilitates exchange and interaction. Institution building and the provision of a framework for well-functioning market structures and organizations are the focus of this approach and it argues for the gradual or incremental implementation of sequenced reforms in order to ensure growing support for policies. Followers of the institutional-evolutionary perspective were critical of the Washington Consensus emphasis on economic, and particularly, monetary variables at the expense of institutional and social variables. Similar criticisms were made of the mathematical precision and overly scientific nature of the economic orthodoxy and the narrowly defined market reforms that follow. In the institutional-evolutionary paradigm, although there is recognition for the need to reduce the role of the state, the emphasis is on a reconstituted state and improving state capacity as opposed to a weakened state. It also stresses the path dependency of system development and is mindful of the historical continuity and the communist heritage unlike the ahistorical, tabula rasa Washington Consensus approach. Critics of the institutional-evolutionary perspective claim that the time lost in waiting for the evolution of the institutions will be too costly, both in political and economic terms. Others concede that although history matters, it is not a reason to oppose, delay, or reverse reforms. Furthermore, policymakers often argued that the political and administrative collapse that accompanied economic transformation meant that the strategy as espoused by the followers of the institutional-evolutionary approach, namely a gradual, sequenced approach, was not possible.

Central Planning and Initial Conditions

Close on 30 countries, from East Germany in the West to China in the East, set out to transform, rather than reform as was the case in the pretransition era, their economic system at the end of the twentieth century. In terms of income per capita, the majority of socialist economies at the beginning of transition were neither low-income countries as prevalent in the developing world of Africa and Southern Asia nor were they high-income countries as predominantly found in North America and Western Europe. Many tended to be middle-income countries (main exception were the Central and East Asian countries, including China) but, often, in later years, with low and declining growth rates. In terms of the economic structure, socialist countries tended to be, on average, urbanized and industrialized with high investment rates and equally high and often inefficient energy usage (World Bank, 1996). In terms of human resources and social indicators, although socialist countries had extensive welfare systems as characterized by relatively even distributions of income, high rates of life expectancy and high literacy rates, there was evidence of a deterioration in living standards as, for example, the economies of the Soviet bloc began to stagnate in the later stages of the Brezhnev era.

The socialist system had a number of distinguishing economic features. These included the centrally planned mechanism of resource allocation, collectivism, and state ownership, and the dominance of industry and investment over services and consumption. Despite the common legacy of one-party rule, public ownership and bureaucratic

coordination, the former socialist countries were not all the same at the outset of transition. Initial conditions varied greatly, not just between the countries of East Asia (including China), Central and Eastern Europe, and the republics of the former Soviet Union (FSU) (Russia included) but even within these groups of countries. Understanding these cross-country variations in circumstances is useful when explaining, at a later stage, the issue of the large variation in economic performance and outcomes that emerged between countries once transformation began. Differences in the starting point may also partly explain the different reform strategies adopted by the various TEs, acknowledging that other factors including political constraints, electoral support and legitimacy, ideologies, institutions, and pressure (or support) from the West also played a role.

State-owned enterprises (SOEs) and firms in market economies are very different production units. Whereas firms in market economies are autonomous decision-making units, SOEs were part of a hierarchical bureaucratic structure comprising central planners, ministries, and enterprises. SOEs, whose aim was to fulfill the plan, were notoriously large, faced little or no domestic or foreign competition and were responsible for the provision of social services. Due to the problems of securing input supplies the vertically integrated enterprises often hoarded labor and materials. Arising from this uncertainty of supply and the endemic shortages that prevailed, many state enterprises were forced to meet their own input needs while also operating in fits and starts. With no alternative supplier, no competition from other enterprises and with no attention or concern for consumer choice or product quality (except in the high-priority sectors) SOEs were far removed from the normal competitive pressures and price signals of the marketplace. Problems at the enterprise level varied from, at best, misdirected (at worst, perverse) incentives to a lack of innovation and risk-taking resulting in inefficiencies, inertia, and complacency. Prices were distorted with information flows inadequate and often inaccurate: the very same information problem that Friedrich von Hayek exposed as far back as the 1940s (Hayek, 1944).

There were attempts, in pretransition days, to decentralize the economic system and, in particular, to reform SOEs. These were mainly targeted at increasing the role of profits, allowing for greater flexibility and autonomy for management, introducing new bonus schemes, establishing Western-style taxes, reducing the number of targets, charging for the use of capital, and liberalizing foreign trade arrangements. Despite these changes, the enterprise sector (as with the socialist system within which it operated) was in crisis on the eve of transformation.

Economic Policies and Reforms

One of the main problems devising policies suitable for post-socialist transformation was the absence of any historical precedence or theoretical framework. Although there were several examples of countries in the twentieth century that had adopted reforms in the face of systemic change and great uncertainty the transformation from a centrally planned economy to a market economy was unprecedented as it required, unlike in many previous cases where dormant or distorted markets had to be revived or corrected, building markets, institutions, and the capitalist system from scratch. Despite this lack of a blueprint for TEs, reforms in the 1990s in the Soviet bloc countries was dominated by the policies of stabilization, liberalization, and privatization, as strongly advocated by the IFIs. It was argued that the distortions and inefficiencies of the old system would be corrected by price, trade, and free-entry liberalization combined with the necessary macroeconomic stabilization. The other part of the 'holy' trinity was the transfer of ownership from state to private hands by a process of privatization. These initial-phase policies (including the provision of a social safety net) formed the basis of the reform package advocated by mainstream economists and the IFIs. The structural and institutional reforms that comprise the second-phase policies include, among others, enterprise restructuring and competition policy, banking and financial sector reforms, labor market and fiscal reforms, and social security and pension reforms.

For some, privatization was the key element in transition. State ownership was a central feature of the socialist system. In transition, privatization was necessary to transfer ownership from public to private hands. It was argued that privatization would, inter alia, eliminate the tendency for SOEs to fulfill political objectives, improve the quality of managers, encourage greater financial discipline, raise much needed revenue for government, and, when combined with other reforms, result, eventually, in an efficient ownership structure. As the 1980s saw a worldwide increase in privatization, it was inevitable that the TEs would follow the privatization route. Even before the Soviet Union broke up, enterprise managers were seeking changes in ownership structures during the so-called 'spontaneous privatization' period. Aside from differences in the number of enterprises undertaking privatization, the form or method of privatization often differed. With inadequate savings, poorly functioning capital markets, 'fuzzy' property rights, underdeveloped legal systems, a plethora of unviable SOEs, a weakened state capacity, public opposition to privatization and reluctant foreign investors, the normal forms of privatization, including individual sell-offs of publicly owned firms, were inadequate and, in many cases, inappropriate. Other issues at the outset of privatization were the speed (versus the quality) of a change in ownership, the role of restitution to precommunist owners, the sequencing of privatization vis-à-vis demonopolization and restructuring, the role of investment funds and the involvement of foreign investors, and the relevant importance of privatization as against the development of *de novo* private firms. There was also some debate on how to deal with the winners and losers that result from privatization and how to provide adequate protection for minority shareholders. Given the scarcity of private capital and the difficulty in valuing enterprises on the eve of transition, a new form of privatization, called mass privatization schemes was initiated whereby shares in enterprises were sold for free or at a nominal fee to a country's citizens, via vouchers, coupons, or certificates, and tradable at auctions. Many TEs, and, in particular, most of the FSU countries adopted the mass privatization schemes as it was viewed as the most politically acceptable. Although supporters of rapid privatization cited the usual economic arguments for doing so,

often the politics of privatization was invoked. Rapid privatization would ensure a depoliticization of economic activity and, in turn, prevent a return to the old state-dominated socialist system, while at the same time, create a demand for market-supporting institutions. However, it became evident in the mid- to late 1990s that all was not well with privatization and that a change in ownership alone was not sufficient to guarantee improvements in enterprise performance. In particular, there were problems with the process and outcomes of privatization in many TEs, including the high profile schemes in the Czech Republic and Russia. Later, it became clear that, among other things, the form that privatization takes matters (despite, at the early stages of transition, advocates of privatization invoking Coase's theorem claiming that the question of how to privatize, and the initial allocation of property rights, do not matter). Well-functioning legal systems and capital markets also matter. Other elements of enterprise reform, including proper corporate governance mechanisms, hardening of the budget constraint, market structure and competition policy, ownership types (foreign vs domestic, concentrated vs dispersed, privatized vs *de novo*) were also found to be important in the empirical studies on the determinants of enterprise restructuring and performance.

Throughout the transition era, debate continued over the most appropriate sequence to reforms, and, in particular, the order of enterprise restructuring versus privatization, enterprise reform versus financial/banking sector reform, institutional reform versus market reforms, (stabilization versus) liberalization versus demonopolization and competition, not to mention the order of economic reform versus democratization. Inevitably, those reforms that were easiest to implement, attracted less opposition from powerful vested interests and were popular in policy circles (including the IFIs of the Bank and Fund) were advocated and implemented first. These reforms included price liberalization and macroeconomic stabilization, with the latter having some notable country setbacks along the way. Those reforms that took longer to implement, attracted most opposition from interest groups and were less frequently championed in policy circles were slower to emerge. These included changes to governance (both at national and corporate levels) and financial sector reform.

Other policy debates that raged throughout the transition era include the relative importance of market reforms (as opposed to initial conditions, external factors or institutional arrangements) in accounting for economic performance, the importance of political constraints, the tightness of monetary policy, the validity of the 'uniqueness' argument in designing country-specific policies, the importance of the lure of the EU (the 'return to Europe' commitment), the role of foreign aid and, not least, the case for and against an investment strategy and an industrial policy. One thing that is clear after decades of reforms is that expectations, after the collapse of the socialist system, with respect to policy reform were unrealistic and overly optimistic. Finally, a number of patterns of reform have emerged since transformation and economic reforms began. Most progress has been made in the initial-phase reforms, and by the Central and Eastern European (CEE) countries and Baltic states whereas much slower progress has been made in the second-phase reforms and by the Commonwealth of Independent States (CIS) countries. Neither China nor Vietnam followed the conventional reform strategy but have implemented, with greater success in terms of outcomes, major changes to their economic system. In terms of enterprise reforms, the big difference between China (where the dual-track approach dominated) and the Soviet Union (where privatization of state enterprises was the main strategy adopted) was the growth of the nonstate sector in China. In particular, rural township and village enterprises (TVEs) have contributed enormously to the success of Chinese reforms. Although there were different types of rural TVEs, they were, in terms of their ownership structure, collectively owned public enterprises under the control of local, as opposed to central, government officials. It was these community-owned local government firms, and not the *de novo* private firms as in CEE countries, that were the initial engine of growth in China's enterprise sector. In more recent years, many TVEs were subject to substantial restructuring, with many changing ownership into privately owned firms.

In summary, although the debate with respect to the speed, nature, and sequencing of reforms dominated the early years of economic transformation, second-generation reforms proved more difficult, and, it is now believed by many, were more fundamental to achieving a successful outcome. Transformation required, at different stages, macroeconomic, structural, and institutional reforms. Stabilization, liberalization, and privatization were necessary but not sufficient conditions to guarantee a return to growth and an improvement in living standards. The institutional underpinnings of the capitalist system are needed for market reforms to work and, ultimately, for transformation to succeed. Sound policies to be effective require a solid institutional setting. Likewise, poor institutions and weak governance will inhibit market reforms. Without these changes, the transformation to the market will remain incomplete and the least-advanced TEs will continue to experience serious coordination problems (Hare and Turley, 2013).

Institutions and Institutional Change

Although there are different definitions of institutions, the most common one is taken from North (1991) where institutions are defined as formal rules, informal constraints, and enforcement mechanisms. Institutions, including the organizations that implement the rules and codes of conduct, are important because they facilitate exchange and govern market transactions. In any setting a stable society requires a set of rules and social norms for behavior. Order in the socialist system was provided by the State and the Communist Party. All else, whether it was public ownership, the central plan, the soft budget constraint or shortages, followed from the one-party system (Kornai, 1992). Although the fall of communism was greeted enthusiastically as a move toward freedom and prosperity, an unanticipated consequence of the collapse of the State and the disintegration of the Party was, at least in the early years of transition, an institutional vacuum filled by disorder, disorganization, and, in some cases, chaos (Djankov et al., 2003). Neither the market, nor the market-supporting institutions emerged overnight. Although markets soon evolved, the institutions that facilitate and support market transactions were often slow to develop. With a weakened state capacity, many

market-supporting institutions were either, at worst, absent or, at best, ineffective. Over time, with the support of a reconstructed state and international assistance, many of the formal institutions and organizations required for a stable society and a growing economy were developed. However, it was the more informal institutions and social norms that, not surprisingly given the influence of culture and history, evolved more slowly. Aside from differences in how these institutions evolved, there was also significant cross-country or cross-regional variation with respect to institutional change. Beyond the initial years of transition, more attention was paid to institutions and institutional reform. Although much progress has been made, there is still a long way to go in improving the institutional quality in many former socialist countries and, most especially, the CIS countries. Nevertheless, given an earlier view that institution building is inevitably a slow process, some countries did manage their institutional construction "… surprisingly quick and successful …," and furthermore, judging against countries of similar levels of economic development, "… institutional scores for transition countries as a whole are no better and no worse than one would expect …," with some "… widespread, large, continuing improvements in institutional quality from 1990 to 2000" but against that, failures were also commonplace, with a significant number of TEs witnessing "slow initial progress … followed by severe regression" (Murrell, 2008).

In summary, with the notable and important exception of China, transformation witnessed the destruction of the institutional structures of the socialist system and an institutional vacuum for much of the early years of transition. As time passed and state capacity improved, institutions were developed and rebuilt, with more progress in CEE countries than in CIS countries. By the end of the second decade, a majority of the former socialist countries had many of the market-supporting institutions common in other emerging markets and the more established market economies. Whereas many TEs transplanted best-practice international institutions, others (particularly China) experimented with transitional institutions. The question of how the quality of institutions can be improved in the laggard transition countries remains an outstanding issue. What is not at issue is the significance of institutions for TEs and, more broadly, the market economy and the capitalist system. As Berkowitz and Roland (2007) wrote "The transition experience has indeed shown with a vengeance the importance of institutions in the process of economic development."

Performance and Outcomes

Some of the outcomes of transition were expected, such as the rise in private enterprise and services, the fall in government expenditure and revenue, the rise in foreign trade and unemployment, and the change in investment and consumption patterns. Others happened as predicted but the degree of the change was unexpected, such as the rapid rise in prices, the sudden fall in revenues, the extreme rise in poverty and inequality. Other developments were, for the majority of commentators interested in economic transformation, surprising. The main surprises, of which the vast majority are negative, include the collapse in output in the early years of transition; the rise in corruption, the mafia, and the unofficial economy; the extent of disorder, disruption, and dislocation; the number of failed privatization outcomes, and associated asset stripping and tunneling; the worsening demographics in CIS countries in the form of falling population numbers (falling fertility and rising mortality); and deteriorating life expectancy for males in the Slavic CIS countries. There is a very large cross-country and regional variation in performance and outcomes. Most notably, this includes the relatively poor performance of Russia as compared with the impressive outcomes achieved in China.

As regards these patterns of transition, there are differences with respect to time and regions/countries. In respect of differences over time, the early years recorded the worst features of transition (notably transformational recession, hyperinflation, rising poverty, and inequality) whereas the second decade of transformation witnessed a recovery until the onset of the Great Recession and the 2008/09 financial crisis. In respect of country and regional differences, the biggest difference is between CEE/FSU countries and the East Asian countries of China and Vietnam. Aside from some similarities, many of the most disturbing trends were not witnessed in either China or Vietnam. Within the Soviet bloc there are also differences, along the lines of CEE (including the Baltics) versus CIS (and within that, energy resources-rich vs energy resources-poor) countries, with the CEE countries doing much better in terms of output, job creation and inflation, poverty and inequality, corruption and demographics. Some of the leading CEE reformers, notably Estonia, Latvia, and Hungary, were badly affected by the 2008/09 financial crisis, leading to questions about the region's development model and, more specifically, the vulnerability of some TEs to global or regional shocks arising from the region's deep integration into the global trade and financial system. The high global liquidity, cheap credit, and speculative capital flows of the mid-2000s resulted in consumption booms, property bubbles, and rising indebtedness in many emerging markets, including some TEs. However, helped by the coordinated policy response of national authorities and international organizations, economic recovery did follow, only to falter shortly after arising partly out of contagion from the Eurozone crisis. Debate continues over the need for greater reforms, determinants of long-run growth and the prospects for income convergence with the most advanced economies in the world (EBRD, 2009, 2013; Mitra et al., 2010).

The empirical research on the determinants of output growth in TEs identifies a number of factors, including initial conditions, macrostabilization, institutions, and policy reforms. Although the evidence is mixed, it appears that there is no one key factor in explaining cross-country differences in economic performance. Initial conditions matter, but less so over time. Macrostability is important but excessive pursuit of low inflation and fiscal restraint may be costly. Market reforms matter but are not a sufficient condition for output recovery. Institutions are important but differences exist as to which institutions are important and the timing of institutional reforms vis-à-vis economic policy reforms.

Despite the cross-country variation in performance, and the disappointing outcomes in some countries and for many citizens (as evident in the Life in Transition Surveys LiTS I and II, see EBRD, 2011), recognition must be given to the

enormous changes that have taken place, and over a relatively short period of time. Aside from the welcome transition to democracy, weak as it may be in some countries, systemic changes of an economic nature include the transformation from the central plan to the market system; state ownership to majority private enterprise; price controls to market forces; large monopolistic enterprises to SMEs and competition; autarky and regional integration to foreign trade and global integration; heavy industry and military production to services and civilian production; and communist Soviet-Sino institutions to, albeit imperfect or incomplete, capitalist institutions. As for economic transformation and the broader transition from central planning to market economy as a separate subbranch of economics, the aforementioned changes have led to questions about the end of transition and economic transformation from plan to market (as distinct from transitology, in general). Although similar questions were raised in earlier years, the passage of time and successive transition anniversaries have inevitably led to reflections on the transformation process, performance outcomes, and reforms and institutional change (see Kornai, 2006; Sonin, 2013; Pistor, 2013). Whether we have seen the end or the next stage of transition, using our time now to reflect on the subject of transformation from central plan to market economy and the broader academic question of its contribution to economics and comparative economic development is a very worthwhile exercise.

Assessment and Lessons

Transformation, however it is defined, is extraordinarily complex, involving wholesale systemic large-scale institutional changes. Economic transformation, combined with the political and social transition, was unprecedented. One consequence of this systemic change is that the discipline of economics now has a greater understanding of capitalism and its institutional foundations, the interplay of politics and economics, and the importance and unpredictability of dynamic changes. In many TEs, policymakers were confronted with the dual problems of transition and development, of emerging markets and destatization, of market reform and institutional reform, of structural adjustment and reconstruction, of political change and economic change, resulting in initial outcomes that included, for the majority of TEs, a large fall in output, rapid inflation, social disruption, and, for many CIS countries, disturbing demographic trends. From an economic theory perspective, the lesson here is the inadequacy of any one school of economic thought to fully explain transformation or to adequately inform policymakers of the complexities of the transition process. Institutions are now considered mainstream, and institutional reform is considered as important to the success of transition as the market reforms that were advocated by the IFIs, policymakers and the majority of influential Western academic economists at the outset of transition. This is a lesson that has relevance beyond transition and TEs, to topics such as the determinants of economic growth, governance of developing and emerging markets, the role of IFIs and the suitability/conditionality of market reforms, etc.

If there was ever an event in the twentieth century that required a political economy perspective, it was the transformation from socialism to capitalism and from plan to market. The interplay between politics and economics is crucial in helping to understand the policy reforms, performance, and outcomes in transition countries. The experience of TEs clearly illustrates the importance of political constraints. Politics matters and the political economy of reform are central to an understanding of transition. Indeed, this practice, and growing trend, of integrating the political process into an analysis of economic issues is more widespread now in economics, into areas such as international trade, public finance, regulation, and others (Roland, 2000). In reforms, political considerations dominate as much as, if not more than, economic deliberations. More generally, the events and outcomes during transition simply reinforce the need for the economics profession today, as was the case in earlier times when the discipline was known as political economy, to emphasis and reiterate the link between economics and politics, as Adam Smith and Karl Marx did centuries ago. Reforms were often not the exogenous choice of policymakers but instead were endogenous, subject to political constraints. Feasibility as opposed to ideology was, in the end, often what determined actual policy reforms. In the tradition of political economy, reforms were often designed based on what was politically feasible and socially acceptable (Turley and Luke, 2010).

Another lesson from the transition experience is the role of the state in the modern capitalist system. Given the extent of state control in the command economy and given the prevailing economic orthodoxy at the time of the collapse of the socialist system, there was inevitably going to be a significant reduction and reorientation in state involvement, both in terms of size and scope. Some commentators, admittedly those closest to the neoliberal perspective, even argued for a dismantling of the state. In cases where this occurred, state collapse and the problem of a weakened state emerged. No doubt, reform of government was necessary. A reconstituted state was required. However, as learned from elsewhere (particularly in the post–World War II era and in the newly industrialized countries (NICs) of South East Asia), markets and governments complement each other. Lessons from individual TEs, both positive and negative (whether it is decentralization in China, enterprise restructuring in Poland, or state collapse in Georgia and Russia), indicate the important role of the state in the capitalist system. Despite the tendency during transition to dismantle the state, it became clear that, in many respects, a strong and effective state was required, albeit playing a much more different (and limited economic) role than before. There was a need to recognize that the state, although less required in many cases (e.g., subsidies from profit to loss-making firms, foreign trade monopolies setting prices, extensive state ownership) other roles for the state were required (e.g., policing competition policy, supporting SME development, countercyclical macro policy, social protection). As we know from international experience, both now and in the past, it is a difficult task to achieve the right balance between a state that is, on the one hand, strong and competent and, on the other hand, constrained and nonpredatory. In the context of TEs, although it was

both inevitable and desirable that the market's role would increase while the role of the state would decline, excessive moves in either direction can be costly. When writing about the importance of time and state guidance in transition, and specifically in Russia, Nobel Laureate Kenneth Arrow (2001) concluded, "Although the role of government in directing economic activity in a healthy economy is limited, transition does require guidance. The only source of general guidance for the economy is the state, and there is no denying that appropriate policy and leadership could considerably smooth transition."

What about Russia and China? Russia is, by all accounts, a market economy. The market is the main coordination mechanism with prices for the majority of goods and services determined by market forces of demand and supply. The private sector share of GDP is close to 70%. However, the postsocialist path to the market economy was difficult and, for many, traumatic. Given Russian and Soviet preconditions, transformation from plan to market in Russia was inevitably going to be complex and arduous; indeed it was. The interesting question is whether it could have been done any less painful. What, if any, were the alternatives? We will never know the answer to some of these questions but what we can do is identify some lessons and policy mistakes. With respect to Russia (and other CIS countries), the lessons from transition are many and controversial. The important specific lessons are that politics matter; market reforms need to be tailored to local conditions and, despite often wrenching circumstances, need to be socially tolerable; the importance of macroeconomic stability; the danger of an institutional vacuum; the importance of effective State capacity; the importance – or absence in the case of Russia – of legitimacy. As for China, the important lessons from the Chinese reforms are not related to the speed of reform (as speed is not the big issue) or to ownership as the Chinese record on privatization has neither caused nor prevented output growth. The interesting and more relevant reforms in China are the change in openness to foreign trade and participation in world markets; emphasis on changing incentives; willingness to, and emphasis on, experimentation, bottom-up reforms, the evolutionary nature of change; decentralization and competition; pragmatism and emphasis, ironically, not on ideology but on what works for economic growth and development. As Deng Xiaoping remarked, "It doesn't matter whether a cat is black or white, as long as it catches mice."

Abstract

This article covers the role of economic theory in advancing our understanding of criminal behavior. We begin by reviewing the history of the economic view of crime, drawing on the work of Bentham and Beccaria, and embracing individual rational behavior. This discussion is followed by a cost–benefit analysis of crime and a general discussion of how 'economics' differs from 'criminology' when explaining criminal behavior and legal policy. The article concludes with a review of recent studies offering economic analysis of crime and justice, as well as avenues to extend this model in future work.

The Economic Theory of Criminal Behavior

Beginning with the work of economics Nobel laureate Gary Becker in 1968, economists have invaded the field of criminology, using their all-embracing model of individual rational behavior. Several of Becker's ideas were foreshadowed by earlier writers – Cesare Beccaria in 1767 and Jeremy Bentham in 1789. These early scholars, though not economists, developed several concepts that would later be associated with the economic theory of criminal behavior: "… the profit of the crime is the force which urges man to delinquency: the pain of the punishment is the force employed to restrain him from it. If the first of these forces be the greater, the crime will be committed; if the second, the crime will not be committed" (Bentham, 1907: 399).

However, from the beginning of the twentieth century interest in their point of view dwindled as a plethora of other theories were developed. Fortunately, the main idea of Bentham was vitalized and modernized in Becker's path-breaking article, Crime and Punishment, where he suggests that "a useful theory of criminal behavior can dispense with special theories of anomie, psychological inadequacies, or inheritance of special traits and simply extend the economist's usual analysis of choice" (Becker, 1968).

In Becker's model, a criminal act is preferred and chosen if the expected benefits from committing a crime exceed the expected costs, including the costs of any foregone legal alternatives. The economic theory of criminal behavior is thus regarded as a special case of the general theory of rational behavior under uncertainty. Assuming that individual preferences are constant, the model can be used to predict how changes in the probability and severity of sanctions and in various socioeconomic factors may affect the amount of crime. Even if individuals who violate certain laws differ systematically from those who abide by the same laws, the former, like the latter, do respond to incentives (i.e., to sanctions and economic conditions). Indeed, numerous empirical studies confirm the predictions of the economic theory.

The Benefits and Costs from Crime

Thus, the economic model of criminal behavior assumes that the decision to commit a crime is the result of a cost–benefit analysis that individuals undertake either consciously or subconsciously. The gains and losses included in the economic model are usually meant to represent all kinds of benefits and costs that have an effect on the people's decisions. People are assumed to allocate time to criminal activity until marginal benefits equal marginal costs. For some people marginal benefits of crime are probably always lower than marginal costs of crime; the economic model would predict that these people will never commit crimes. For others, the marginal benefits often exceed the marginal costs; we would expect these people to specialize in crime. For most of us, the marginal costs usually exceed the marginal benefits. However, every once in a while the marginal costs seem particularly low or the marginal benefits seem particularly high, and we commit a crime. For example, we may be driving on a stretch of country road where police seem unlikely (low marginal cost of speeding) or we are driving a Ferrari (high marginal benefit of speeding) so we decide to speed.

The kinds of gains obtained from a criminal act vary, depending on the type of crime and the individual criminal. Some are monetary, such as the gains obtained from theft, robbery, insurance fraud, killing a rival drug dealer, etc. Others are psychic, such as the thrill of danger, peer approval, retribution, sense of accomplishment, or 'pure' satisfaction of wants (rape). Obviously, the psychic benefits from crime will be different for different people: young men tend to enjoy the thrill of danger more than older women and gang members tend to get more peer approval than churchgoers when they commit a crime. Incarcerated criminals may also gain human capital in committing future crimes if they learn techniques from other criminals or meet future potential crime partners while imprisoned.

The costs of crime also depend on the crime and individual. The costs can include direct material costs, psychic costs, opportunity costs, and expected punishment costs. The material costs include the cost of supplies purchased to commit crimes (equipment, guns, vehicles, face masks). Psychic costs include any guilt, anxiety, fear, dislike of risk, or other emotions associated with committing crime. The opportunity cost of crime consists of the net benefit of the legal activity forgone while planning, performing, and concealing the criminal act. The lower an individual's level of income, the lower is his or her opportunity cost of engaging in illegal activity. The amount a person can earn in the legal sector may depend on factors such as age, sex, race, education, training, region, rate of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45057-9

unemployment, and IQ. People who are only able to earn a low wage will have a low opportunity cost of crime, as they are not giving up substantial legal income.

The expected punishment costs include the cost of all formal and informal sanctions, as well as the pecuniary costs arising from litigation (lost income and lawyers' fees). When the formal sanction is a fine, the punishment cost is the amount of the fine. When the formal sanction is a prison term, the punishment cost incorporates the cost to the criminal of going to prison: the lost income, the monetary equivalent of the loss of liberty, the monetary equivalent of whatever harms come to the individual while in prison, etc. The costs of the informal sanctions result from the social stigma that accompanies arrest, conviction, and imprisonment. These sanctions can include the reactions of employers, family, and friends and the reduced legitimate income a criminal will earn once he or she has a criminal record. These expected punishment costs must be weighted by the probability that the individual will be arrested, convicted, and imprisoned. An individual facing a 50% chance of receiving a 10-year prison sentence has higher expected punishment costs than an individual facing a 5% chance of the same prison sentence. The probability of punishment will be different for different people. Some are cleverer than others at concealing the offense and eluding the police. There are also differences in the abilities of defending oneself in court, or in engaging good lawyers (Hoffman et al., 2005). That is to say, to estimate the expected penalty that a particular individual faces, we multiply all costs of punishment by the probability of receiving those punishments.

The Stigma of Criminal Activity

The stigma from criminal activity can be social (inability to find a spouse) or economic (inability to find a job with a criminal record). Several scholars have attempted to measure the economic stigma. Lott (1992) finds a short-run income reduction of 39% after a bank embezzlement conviction and a 41% reduction after a bank larceny conviction. Grogger (1992) finds that an arrest record can explain about two-thirds of the black–white youth employment differential in his sample. However, in another study, he finds only a short-lived effect of arrest records on youth earnings (Grogger, 1995). For gang members, having spent time in prison may actually increase future incomes.

The Criminal's Discount Rate

The rate at which individuals discount the future also affects the expected benefits and costs from criminal activity. The gains from crime often occur immediately, whereas punishment is something that might come in the future, and be stretched over a long period of time. An individual with a high discount rate will therefore tend to commit more crime because he or she weighs the present (and the gains from criminal activity) much more heavily than the future (and the potential costs from criminal activity).

The Economic Theory of Recidivism

Recidivism is sometimes explained by erratic behavior, a lack of self-control, or evidence that the deterrence model does not work. However, a high rate of recidivism is consistent with the model of rational choice. Serving time in jail may reduce legal opportunities so that the opportunity cost of future criminal activity is lower. Additionally, convicts may acquire human capital in illegal activities – prison is an excellent place to 'network' with other criminals and learn the skills of the trade. Thus, if it was rational to commit a crime in the first place, for many criminals the incentives will only be stronger after having served a prison sentence.

In contrast, a prior conviction or imprisonment might increase some criminals' evaluations of how probable or severe sanctions might be. For these criminals, the expected costs of additional crime may be higher than the expected costs accompanying their initial crime and they will tend not to recidivate.

Economics versus Criminology

How does the economic approach to criminal activity differ from the criminology approach? The criminological literature is essentially composed of three branches. One branch focuses on the biological factors contributing to crime, such as brain abnormalities or hormonal imbalances. The economic approach does not deny that biological factors matter; it just assumes that these factors explain the baseline level of crime that exists regardless of the incentives created by other costs and benefits of criminal activity. The second branch of the criminological literature asserts that people turn to crime when they are prevented from reaching their goals through legal means. This assertion is consistent with the economic model that predicts that people with limited legal opportunities may turn to crime. However, the economic approach, in contrast to the criminological approach, predicts that individuals weigh the relative costs and benefits of crime and legal activities, and only engage in crime if it is relatively more attractive. The third branch of the criminological literature is concerned with the social interactions through which criminal behavior is learned or culturally transmitted. This approach is also consistent with the economic model that maintains that community influences and cultural factors can influence various costs and benefits of crime: an individual committing a crime may feel less of a stigma (a cost of crime) or even gain approval (a benefit) depending on how others in his or her social circle views criminal activity; an individual may feel more or less internal guilt (a cost) depending on their religion or community; individuals may learn smarter criminal tactics when they associate with other criminals. Thus, the economic model of crime, for the most part, encompasses many of the criminological explanations for crime. The difference between the two approaches is mainly one of emphasis (see Levitt and Miles, 2007).

There is also a branch of criminology that stresses the implications of everyday activities on crime. For example, as more women enter the labor force there are more vacant houses and so perhaps more burglaries. As more people carry cell phones the ability to contact police increases and so crime may be reduced (Felson and Santos, 2009). This is also consistent with the economic model: everyday activities can affect the gains from crime or the expected punishment, and in turn, the level of crime.

Are Criminals Really Rational?

The economic approach posits that everyone (except, perhaps, individuals with severe mental disabilities) responds, to some

degree, to changes in the expected costs and benefits of criminal activity. Several authors have discussed whether people have sufficient information about the environment and about outcomes of actions to make rational choices. Becker and others maintain that even if choices are based on subjective beliefs that are wrong, the choices are meaningful from a subjective point of view, and behavior can be explained and understood on this basis. Moreover, even if people are not exactly accurate in their estimation of the expected benefits or costs of criminal activity, an obvious increase in an expected cost of crime or decrease in an expected benefit of crime should still influence (albeit imperfectly) the incentives to commit crime.

Empirical Studies of the Economic Model of Crime

Predictions from the economic model of crime have been tested in a great number of empirical studies. However, these empirical studies face several challenges. First, although the economic model of crime is based on individual rational choice, the data available to empirical researchers are based on levels of aggregation ranging from countries and states down to municipalities and campuses. Thus, the empirical results can tell us only about general deterrence – the effects on people in general – rather than the effects on an individual's decision-making.

Second, it is extremely difficult to identify causal relationships in empirical studies of crime. For example, in testing the relationship between imprisonment and crime, one may find a positive relationship (imprisonment and crime increase together or decrease together). Based on these results, some scholars may conclude that prison increases crime, when in fact, the positive relationship may be attributable to higher crime rates producing more potential prisoners.

Controlling for the factors that lead to high crime could solve the problem, but it is impossible to quantify and control for every factor, so omitted variable bias can be a problem. More recent empirical studies have devised clever ways to tease out causal relationships, for example, by taking advantage of exogenous changes in imprisonment levels, such as court-ordered prison releases, that could not be caused by crime (Levitt, 1996).

The third challenge is the difficulty in distinguishing incapacitation and deterrence. The economic model of crime assumes that increases in imprisonment increase the expected costs of crime and deter some individuals from committing crimes. However, an empirical finding that increases in imprisonment are associated with decreases in crime might not be evidence of deterrence. Crime could also decrease because more criminals are behind bars due to the increased imprisonment. Although the end result is the same, the rational choice model assumes that individuals can be deterred from committing crime. Thus, if the entire decrease in crime was caused by incapacitating criminals, this would not confirm the predictions of the economic model of crime.

There are various other challenges that involve the correct variables to control for in empirical analyses, the particular methodology to employ, and other sophisticated empirical questions. Nevertheless, the awareness of the methodological problems and easier access to various statistical methods has gradually led to more sophisticated empirical studies that address several of these challenges.

Cognizant of these empirical challenges, law and economics scholars have studied the relationship between crime and various costs and benefits of criminal activity. Summarizing the entire empirical literature, which consists of thousands of articles, is beyond the scope of this article, but below we discuss the general consensus or important articles studying the effects of different variables.

Police

The majority of empirical studies find that policing levels have a large negative relationship with crime (see, e.g., Di Tella and Schargrodsky, 2004; Corman and Mocan, 2000; Levitt, 1997).

Imprisonment

Most studies find that imprisonment also has a negative effect on crime rates. Some of this effect is due to deterrence and some is due to incapacitation (see, e.g., Levitt, 1998; Kessler and Levitt, 1999). Severe prison conditions also have a deterrent effect (Katz et al., 2003).

Capital Punishment

The effect of capital punishment continues to be hotly debated. The majority of empirical papers find a deterrent effect of capital punishment (see, e.g., Dezhbakhsh and Rubin, 2011; Dezhbakhsh et al., 2003; Mocan and Gittings, 2003). Some studies have found that the deterrent effect exists only in some states (Shepherd, 2005). Others argue that the deterrence finding is extremely sensitive to methodological choices in the empirical analysis (Donohue III and Wolfers, 2006).

There is a tendency to conflate findings regarding capital punishment with general issues of deterrence. In the contemporary US capital punishment is rare and unpredictable. It could be that the rarity of this punishment reduces or even eliminates the deterrent effect. It is also possible that its rarity means that statistical methods are unable to detect a deterrent effect even if one exists. Nonetheless, even if we cannot detect a deterrent effect of capital punishment, this does not mean that more normal punishments such as jail time do not deter.

Gun Laws

The effect of gun laws on crime is also hotly debated. Some studies have found evidence that laws allowing citizens to carry concealed handguns decreases crime; presumably the possibility of encountering a victim with a gun deters potential criminals from committing crime in the first place (Lott, 2010; Lott and Mustard, 1997). In contrast, other studies find that gun laws do no decrease crime (Ayres and Donohue III, 2003; Dezhbakhsh and Rubin, 1998).

Income

No systematic relationship appears between various measures of income and crime. Several studies find that high legitimate wages (an opportunity cost of crime) are associated with low

crime rates (Machin and Meghir, 2000; Cornwell and Trumbull, 1994). On the other hand, some studies find that higher pecuniary benefits to crime (a benefit of crime) are associated with increases in crime (Glaeser and Sacerdote, 1999). This ambiguity in results is likely due to the fact that the income measures used represent benefits not only of legal activities, but also of illegal ones: higher legal incomes tend to make work more attractive than crime, but to the extent that higher legal income in a region produces a greater number of more profitable targets for crime, crime also becomes more attractive. If these mechanisms are at work simultaneously, and their relative strength is not universally constant, it is not surprising that the results of various studies differ.

Income Inequality

A large income differential may indicate that crime is a comparatively rewarding activity for the very-low-income group that may find a lot to steal from the very rich. Nevertheless, empirical studies also find no systematic relationship between income inequality and crime. Several studies find that greater income inequality does lead to increases in crime (Fajnzylber et al., 2002). In contrast, others find no statistically significant relationship between income inequality and crime (Neumayer, 2005).

Unemployment

Unemployment is a measure of the lack of legal income opportunities; the unemployed have lower opportunity costs of crime as they are not giving up legitimate employment. The majority of studies find that higher rates of unemployment correlate with higher levels of crime (Gould et al., 2002; Raphael and Winter-Ebmer, 2001).

The Economics of Law Enforcement

The economic theory of public law enforcement is based on a specific perception of justice as efficiency. Under this perception, the purpose of public law enforcement is to maximize social welfare, where social welfare is the benefits that individuals obtain from crime minus the costs of committing crime, the costs of harm to victims, and the costs of enforcement. The government can maximize the social welfare function through three policy instruments: the probability of capture and punishment, the length of prison terms, and the level of fines. In setting these policy instruments at their ideal levels, the economic model assumes that criminals behave rationally and weigh the costs and benefits of criminal activity before turning to crime.

Deterrence is the goal in the traditional economic model of public law enforcement. The optimal amount of deterrence occurs at the point where the marginal social cost of additional deterrence equals the marginal social benefit. (Following most of the literature, we focus on optimal enforcement when deterrence is a goal. Incapacitation as a goal has received much less attention. See Shavell (1987) for a discussion of optimal enforcement when incapacitation is a goal.) Thus, under the traditional definition, efficient deterrence balances the marginal costs of enforcement and the reduction in illegal gains to criminals against the marginal benefit of enforcement, which is the reduction in harm that results from enforcement. Thus, deterrence is inefficient if the marginal gains to criminals plus marginal enforcement costs exceed the marginal harm to victims.

However, many researchers have questioned whether the gains to criminals should be considered (Lewin and Trumbull, 1990). If we ignored these gains, optimal deterrence would occur at the point where the marginal enforcement costs equal the marginal enforcement benefits (which is the marginal harm to victims). With fewer costs of deterrence to consider (i.e., ignoring the reduction in criminal gains that results from deterrence), the optimal level of deterrence increases.

We begin with the optimal law enforcement choices between probability and severity and between fine and imprisonment in the basic model. Then we consider several extensions of the basic model.

Certainty versus Severity

Law enforcement can influence various policy instruments to achieve the optimal level of deterrence: the probability of punishment, the length of prison terms, and the level of fines. The probability of punishment depends on policing levels, arrest rates, conviction rates, imprisonment rates, funding for law enforcement, funding for courts and prosecutors, etc. In the economic model of law enforcement, the probability of punishment is often referred to as the *certainty* of punishment. In contrast, the length of prison terms and level of fines, which law enforcement can also influence, are referred to as the *severity* of punishment.

In his or her decision to commit a crime, a criminal's expected penalty is the product of the certainty of punishment and the severity of punishment. **Table 1** shows several combinations of certainty and severity (presented as either a fine or the cost of imprisonment) that produce identical expected penalties.

If potential offenders are risk neutral and have no wealth constraints, all of the combinations of probability and severity should produce identical levels of deterrence. However, more severe sanctions are cheaper for society to implement. Increasing a monetary fine imposes almost no additional collection costs; rather, it generates additional revenue for society. In contrast, increasing certainty requires more resources spent on police and courts, which can dramatically increase society's costs. Thus, a low probability/high fine combination will achieve the same deterrence as a high probability/low fine combination, but at much lower cost to society.

Table 1 Combinations of certainty and severity with identical expected penalties; the risk-neutral case

Probability of sanction (%)	*Severity of sanction*	*Expected penalty*
100	100	100
50	200	100
25	400	100
10	1000	100

In contrast to fines, increasing the severity of imprisonment imposes significant costs on society that include the costs of running a prison (estimates suggest that it costs $40 000 a year to house a prisoner), the productivity costs of removing a criminal from society (assuming he or she provided some positive benefits to his or her community), and any psychic or stigma costs the criminal experiences while imprisoned. Despite these significant costs associated with imprisonment, it may still be relatively cheaper to increase the severity of imprisonment than to increase the probability of sanctions. Although the longer prison sentences increase enforcement costs, fewer individuals are imprisoned, which decreases enforcement costs and offsets some of the increase from longer sentences. In the linear case, these exactly balance – one person serving 10 years has the same cost at 10 people serving 1 year each.

Thus, regardless of the form of sanction, low certainty/high severity is, in general, the optimal combination because it achieves deterrence at the lowest possible cost (Polinsky and Shavell, 1984). Factors that may contradict this generality are discussed below, but first we discuss the optimal choice of fines versus imprisonment.

Fines versus Imprisonment

Criminal sanctions can be monetary or nonmonetary. As we discussed in the previous section, fines impose little cost on society, and even generate revenue. In contrast, imprisonment imposes substantial enforcement costs on society. Thus, fines are the preferred sanction.

However, a combination of fines and imprisonment is necessary in many situations. If a fine exceeds an individual's wealth level, then the individual's expected penalty will be less than the expected penalty that law enforcement anticipated when selecting the probability and severity of sanctions. For example, in **Table 1**, a probability of 10% and a fine of $1000 for an individual with a wealth level of only $500 will achieve an expected penalty of only $50 instead of $100. Since criminals tend to be those with low opportunity costs of committing crime, for many types of crime it is likely that criminals' wealth levels will be insufficient to achieve optimal deterrence.

When there are wealth constraints, the fine should be set as high as possible, equal to the individual's wealth level. A prison sentence should also be imposed to bring the expected penalty to the desired level. Empirical studies indicate that there is a tendency to impose larger fines and shorter prison sentences on wealthy defendants, although there could be several reasons for this result (Meade and Waldfogel, 1998).

Extensions of the Basic Model

According to the basic economic model of law enforcement, sanctions should be as high as possible and probabilities should be as low as possible to achieve a given level of deterrence. However, this low certainty/high severity combination is not always optimal.

Risk Preferences

When criminals are either risk averse or risk loving, the low certainty/high severity combination may no longer be optimal.

First, consider the case where individuals are risk averse in sentences so that their disutility of the expected penalty rises more than in proportion to the expected penalty. In the case of prison sentences, this could result from an increasing desire for freedom or growing distaste for the prison environment as the time in prison increases (Polinsky and Shavell, 2005: 22). Risk-averse individuals prefer a certain penalty, f, to an uncertain penalty with a mean of f.

Table 2 shows several combinations of certainty and severity (presented as either a fine or the cost of imprisonment) that produce the same disutility, but have different expected penalties. In contrast to the risk-neutral case where combinations with equal expected penalties produce equal deterrence, when severity increases for a risk-averse individual, combinations with lower expected penalties produce equal deterrence.

If **Table 2** referred to fines, it is not clear that a low certainty/high severity combination, such as a 1% probability of a $1000 fine, is more optimal than the other combinations in **Table 2**. Although enforcement costs are low, the expected fine, and therefore fine revenue is also low. If the decrease in fine revenue is greater than the savings in enforcement cost, the high fine combination could be a more expensive combination from society's perspective (Polinsky and Shavell, 1979; Kaplow, 1992).

In contrast, if the sanctions in **Table 2** were prison sentences instead of fines, then low expected sentences would not be costly. That is, the 1% probability of a 1000-day sentence has both low enforcement costs and low imprisonment costs. Thus, when offenders are risk averse, the high sentence/low probability combination is unambiguously the optimal combination.

Next, consider the case when offenders are risk loving in sanctions; their disutility of the expected penalty rises less than in proportion to the expected penalty. In the case of prison sentences, this could occur for several reasons: if the disutility from the stigma of prison does not increase with the length of imprisonment, if more brutalization of prisoners occurs at the beginning of a sentence, or if discounting of future disutility makes earlier years in prison seem worse than later years (Polinsky and Shavell, 2005: 23). Risk-loving individuals prefer an uncertain penalty with a mean of f to a certain penalty, f.

Table 3 shows several combinations of certainty and severity (presented as either a fine or the cost of imprisonment) that produce the same disutility, but have different expected penalties. In the risk-loving case, as severity increases, combinations with higher expected penalties produce equal deterrence.

If **Table 3** referred to fines, then the optimal combination of certainty and severity would be high fine and low probability.

Table 2 Combinations of certainty and severity with identical disutility; the risk-averse case

Probability of sanction (%)	*Severity of sanction*	*Disutility of expected penalty*	*Expected penalty*
100	100	100	100
40	200	100	80
10	400	100	40
1	1000	100	10

Table 3 Combinations of certainty and severity with identical disutility; the risk-loving case

Probability of sanction (%)	*Severity of sanction*	*Disutility of expected penalty*	*Expected penalty*
100	100	100	100
60	200	100	120
40	400	100	160
30	1000	100	300

This combination would achieve the same deterrence as other combinations, and the expected fine, or fine revenue, would be high and enforcement costs would be low.

If Table 3 referred to prison sentences, then the optimal combination may not be the long sentence/low probability combination. Because the increase in prison sentences is proportionally larger than the decrease in the probability, the expected penalty, or expected prison term rises. If the cost of longer imprisonment exceeds the savings in enforcement costs, then the long sentence/low probability combination would not be the cheapest way to achieve deterrence (Polinsky and Shavell, 1999).

Marginal Deterrence

The low certainty/high severity combination may also not be optimal if the goal is marginal deterrence. If penalties for all offenses are set at their maximal level, there is no reason to not commit a more serious offense. If an individual decides to mug someone, he or she might as well shoot the victim and other potential witnesses; murder carries no additional penalty and killing witnesses reduces the probability of being caught. Instead, the severity of sanctions should increase with the seriousness of the crime. Thus, the penalty for mugging should not be set at its maximal level; it should be set sufficiently below the penalty for murder so that the higher penalty for murder will provide an additional deterrent. Although the lower expected penalties will increase lesser crimes, the reduction in harm from the decrease in more serious crimes will more than offset the increase in harm from the lesser crimes, increasing social welfare.

Repeat Offenders

The low certainty/high severity combination may also not be optimal for first-time offenders so that there is room to increase the sanction if those offenders become repeat offenders. There are several reasons why it may be optimal to increase sanctions for repeat offenders. First, a prior criminal record signals that an individual has a higher propensity to commit criminal acts because either the costs of crime are lower for him or her or the benefits of crime are higher. Thus, higher sanctions are necessary to deter these high-risk offenders (Polinsky and Rubinfeld, 1991). Second, imposing higher sanctions on subsequent crimes increases the cost of committing first offenses; not only does a first offense carry an immediate penalty, it also increases future penalties. Thus, higher sanctions for subsequent crimes may deter first crimes (Polinsky and Shavell, 1998). Third, a repeat offender has already suffered the social stigma of conviction from the first offense. The cost of committing subsequent crimes is less because they do not carry the potential cost of social stigma. Thus, other costs of subsequent crimes, like the expected sanction, must be increased to maintain deterrence (Miceli and Bucci, 2004). Finally, repeat offenders may be better able to avoid detection and apprehension of subsequent crimes because they understand the system and have a larger criminal network. If the probability of punishment is lower for repeat offenders, the magnitude of punishment must be higher to maintain deterrence (Polinsky and Rubinfeld, 1991). In reality, repeat offenders are typically punished more severely than first-time offenders for the same offense. However, some scholars have presented theories where it may be optimal to lower sanctions for repeat offenders (see Burnovski and Safra, 1994; Polinsky and Rubinfeld, 1991 for a discussion).

Conclusion

This article is a summary of a very large body of research. It is impossible to summarize what is itself a summary. But we can say that Gary Becker's (1968) paper has been enormously successful in that it has led to a huge body of research which has greatly enriched our understanding of crime and criminal behavior, leading to significant improvements in policy.

Abstract

The links between ethics and economics are multifarious, and run in both directions. Much of economics is a sort of applied ethics, and is founded on ethical theories. Conversely, economists have contributed to the development of ethical thinking. Preference-based utilitarianism, which was developed by economists, has proved influential in utilitarian thinking generally. Tools from economics that have proved useful in ethics include utility theory, game theory, and social choice theory. Economists and moral philosophers share an interest in many particular topics, including the value of human life and the value of equality.

Introduction

The economy is a central component of society. To a large extent, it determines our well-being, freedoms and opportunities, social connections, health, and many other features of our lives. To a large extent, it also determines how equally or unequally these things are distributed across people. Indeed, the economy is perhaps more important than anything else in determining how our lives go. Consequently, an essential task for ethics is to assess how well the economy is doing and how it might be improved.

This is a task within applied ethics. However, since the working of the economy is complex, and the science of economics is technical, few philosophers have the skills needed to progress far with it. It commonly falls to economists instead. The branch of economics that is devoted to the ethical assessment of the economy is known as *welfare economics*. It is also a branch of applied ethics. Because of its particular subject matter, it has its own special methods, but because it is applied ethics, it needs some foundations in ethical theory. Inevitably, welfare economists working back toward the foundations of their subject have encountered moral philosophers working forward toward applications of theirs. Several topics lie within the domains of interest of both welfare economists and moral philosophers. Section Shared Topics gives some examples.

When they look for foundations for their work, many welfare economists have simply adopted an existing ethical theory. They have formalized it – sometimes distorting it in the process – and applied it to their subject. One example comes from the theory of 'optimal tax,' which flourished in the 1970s. Optimal tax theorists tried to devise a scheme of taxation that would best achieve a particular objective. They took the objective from ethical theory. Some (e.g., Mirrlees, 1971) adopted the utilitarian objective of maximizing the total of people's well-being; others (e.g., Phelps, 1973) adopted the 'maximin' objective of maximizing the well-being of the worst-off person. The latter group was inspired by the publication in 1972 of John Rawls's *A Theory of Justice*. However, they distorted Rawls's view: Rawls himself favored maximizing the worst-off group's access to 'primary goods,' rather than the worst-off person's well-being.

Other welfare economists have been less passive and more critical in their attitude to ethical theory. They have themselves contributed to the theory's development. They have found that the methods of economics are useful equipment for doing so. Like most of economics, welfare economics is a rather formal discipline, and it has evolved a range of formal tools to serve its purposes. These tools contribute to the ethical assessment of economies, but they have turned out to be useful for other ethical purposes too. Moreover, theoretical tools from other branches of economics have also turned out to be useful in ethics. Section Tools for Ethics gives examples of formal methods developed in economics that can be useful in moral philosophy.

In sum, the connections between economics and ethics are multifarious, and run in both directions. It is therefore not surprising that many important moral philosophers have also been important economists. Adam Smith, Karl Marx, John Stuart Mill, and Henry Sidgwick are examples from the past. As a general rule, economist-philosophers have been utilitarians. Economists in general, too, have generally shown utilitarian inclinations. Since the rise of 'classical' economics in the eighteenth century, economists have mostly been concerned with increasing the well-being of the people – a concern that is utilitarian in a broad sense.

Liberalism is another philosophy that is closely associated with economics. Most liberal economists are liberal for instrumental reasons. Their liberalism derives from their utilitarianism; they believe that economic freedom is a good way to promote people's well-being. For example, in *The Wealth of Nations*, Adam Smith (1776) argued that extensive free trade deepens the global division of labor, which in turn leads to economic growth, which is good for people. More recently, a similar conclusion has been drawn from some theorems in welfare economics. The theorems show that free economic competition leads to *efficiency*, defined in a special way, and this sort of efficiency is held to be generally beneficial. However, there are many occasions when economic freedom is clearly not generally beneficial. For instance, monopolies may use their power to delay innovations, and companies freely pursuing their own profit may damage the environment. In these cases, economists are typically in favor of restricting freedom by regulation. This shows that their support for freedom is only instrumental and conditional on its promoting well-being.

Utilitarianism, understood broadly, remains the dominant moral philosophy of economics. However, within economics,

utilitarianism has been radically altered as a result of the progress of economic theory. So close is the association between economics and utilitarianism that these changes have strongly influenced the progress of utilitarian thinking as a whole. Sections Utility Theory and Utilitarianism and the Pareto Principle outline the development of utilitarianism within economics.

Utility Theory

Utilitarianism is an ethical theory, but its development within economics has largely been driven by the development of an associated psychological theory, which has come to be called *utility theory*. Utility theory is the economist's core account of people's behavior. This section describes it, and Section Utilitarianism and the Pareto Principle describes its influence on economists' moral theory.

Utility theory says that each person chooses his/her actions so as to maximize his/her utility. 'Utility' is a term of art, which can be defined in various ways, and different definitions lead to very different versions of utility theory. This has allowed the theory to undergo a major metamorphosis in the course of two centuries.

Utility theory's origin may plausibly be traced to an article by the mathematician Daniel Bernoulli, published in 1738. Bernoulli thought that each person acts to maximize his/her *emolumentum*. (He wrote in Latin.) *Emolumentum* may be translated as 'benefit' or 'advantage,' so Bernoulli held a version of utility theory in which utility is benefit or advantage. Later, Jeremy Bentham (1798) made a more specific assumption that each person acts to maximize his/her pleasure, counting pain as negative pleasure. He held a version of utility theory in which utility is pleasure. (Bentham himself used the term 'utility' differently, to apply to whatever is conducive to pleasure rather than to pleasure itself.)

Utility theory became important in economics only in the 1870s, when the so-called neoclassical school rose to dominance. This was the time when economists first took a serious interest in the behavior of consumers, and utility theory was the theory of behavior they adopted. At the beginning of the neoclassical school, the economist William Stanley Jevons (1871) explicitly took his utility theory from Bentham and went far beyond Bentham in his analysis.

Like Bentham, Jevons thought that each person acts to maximize his/her pleasure. In defense of this view he said, "Call any motive which attracts us to a certain course of conduct, pleasure … and it becomes impossible to deny that all actions are governed by pleasure." Jevons evidently hoped to make his theory of behavior as nearly as possible true by definition. Later economists followed his lead. In the 1930s, in the course of a movement in economics known as *ordinalism*, it took them to a radically different version of the theory. The doctrine of ordinalism was proclaimed by Lionel Robbins in 1932. Ordinalist utility theory was formally set out in a pair of articles by John Hicks and R. G. D. Allen (1934). It was refined by later work into what is best called *axiomatic utility theory*. This is the version that is generally presented in textbooks of economics today.

Axiomatic utility theory is a theory of *preferences*. It assumes a person has preferences among all the alternative acts he/she might do. It treats a preference as a disposition to choose: to prefer one act to another is to be disposed to choose the first over the second if faced with a choice between them. The theory assumes that a person's preferences satisfy a number of axioms. Provided they do so, a formal proof shows that a mathematical function called a *utility function* can be defined to *represent* the preferences in a particular sense. The utility function assigns a number called a *utility* to each of the acts, and it does so in such a way that one act is assigned a greater utility than another if and only if it is preferred to the other. This is the sense in which the function represents the preferences. The dispositional definition of preference ensures that, when faced with a choice between two acts, the person always chooses the one he/she prefers. This one has the greater utility. Therefore, we may conclude that the person always acts to maximize his/her utility. In this way, utility theory is confirmed, but only because a person's utility is defined in such a way as to make it true. Utility is defined as what the person maximizes.

Bernoulli and Bentham's utility theories made substantive commitments about what a person maximizes, whereas the axiomatic theory does not. It is not committed to hedonism, or even to an assumption that people always act self-interestedly. Since the commitments of earlier theories were not very plausible, this was a significant advance in economics.

In a sense, ordinalism made utility theory true by definition. However, it did retain some substantive commitments. It is not always possible to define a utility function for a person in a way that makes him/her a utility maximizer. We can only be sure this is possible if the person's preferences satisfy the axioms of the theory. This is the theory's commitment: preferences satisfy the axioms. In effect, the axioms ensure that the person can be construed as maximizing something, and utility is defined as what she maximizes.

The principal axiom is *transitivity*: if one alternative is preferred to a second, and the second to a third, then the first is preferred to the third. If a person's preferences are transitive, they constitute an *ordering* of the options. The utility function represents this ordering. It puts the options in the same order as the preferences do. Any utility function that puts the options in this same order will represent the preferences equally well. Consequently, many different utility functions can represent the same preferences. The only significant feature of a utility function is its ordering of the options. A utility function defined this way is said to be *ordinal*, hence the name 'ordinalism.'

Axiomatic utility theory was later extended by John von Neumann and Oskar Morgenstern (1944) and by Leonard Savage (1954), independently of earlier work on the same lines by Frank Ramsey (1931). The extended theory recognizes that the outcome of an act is normally uncertain. It assumes that a person's preferences among acts are determined by the possible outcomes that may result from each act, and by the likelihood that they will result. It assumes that the preferences satisfy the same axioms as before, and also some more axioms that are concerned with the pattern of outcomes that may result from each act.

As in the simpler theory, a theorem shows that the preferences can be represented by a utility function. However, because the extended theory makes more assumptions, it is able to establish stronger conclusions. In the extended theory, the utility function assigns utilities both to acts and to their

possible outcomes. As before, one act is assigned a higher utility than another if and only if it is preferred. The special feature of the extended theory is that the utility of an act is the *expected utility* of its possible outcomes. (Expected utility is defined as the sum of the utilities of the possible outcomes, each multiplied by the outcome's probability.) Let us call this the 'expectation property' of the utility function. It means that, of two acts, the person always prefers the one that has the greater expected utility. That is to say, she maximizes expected utility. Once again, this is only because of the definition of utility. Provided a person's preferences satisfy the axioms, the person can be construed as maximizing the expectation of something, and utility is defined as that thing.

The extended theory is known as *axiomatic expected utility theory*. An important feature of it is that the utility function that represents preferences is not merely ordinal. Within the theory, a utility function order not only acts in accordance with the preferences but also has the expectation property. This turns out to imply that differences – increases or decreases – in utility can be significantly compared with each other. Many different utility functions can still represent the same preferences. However, if, according to one of these functions, the difference between the utilities of one pair of acts is greater than the difference between the utilities of another pair, then the difference is also greater according to any other function that represents the same preferences. A utility function in which differences of utility are comparable is said to be *cardinal*.

Utilitarianism and the Pareto Principle

Utilitarianism in a broad sense is simply a concern to promote people's well-being. More precisely understood, it is the view that one ought to act so as to maximize the arithmetic total of people's well-being. Important consequences follow from the precise version that does not follow from the broader one. For example, suppose we assume that the richer a person is, the less the extra well-being he/she will gain from adding an extra dollar to his/her wealth. This plausible assumption is known as *diminishing marginal benefit of wealth*. An argument in favor of equality can be derived from it together with precise utilitarianism. Diminishing marginal benefit implies that rich people generally derive less benefit from extra money than poor people do. Therefore, as extra money becomes available, it adds more to the total of well-being if it goes to the poor rather than to the rich. Precise utilitarianism therefore favors sending money toward the poor. This argument for equality is subject to important limitations, but it was nevertheless a significant contribution that economics made to utilitarian thinking. It was popular among economists before the 1930s, including Alfred Marshall (1920) and A. C. Pigou (1932).

However, the arrival of ordinalism brought skepticism about the measurement of well-being. If we are even to make sense of precise utilitarianism, we must be able to make sense of an arithmetic total of well-being. Two conditions are necessary for that. First, each person's well-being must be an arithmetic quantity. To be more precise, it must be a cardinal quantity, which is to say that differences – increases or decreases – in a person's well-being must be significantly comparable with each other. Second, differences in one person's well-being must be significantly comparable with differences in any other person's: we must be able to say whether a particular increase or decrease in one person's well-being is greater or less than a particular increase or decrease in another's. Ordinalism made economists skeptical about both these conditions.

The source of their skepticism was epistemic. The ordinalists regarded a person's preferences as observable in principle. Since they defined utility to represent preferences, they regarded utility too as observable in principle. Because of this, they assigned ordinal utility a high epistemic status; Robbins called it a 'scientific' concept. However, they were much more doubtful about other features of a person's psychology.

What about well-being? The ordinalists seem to have taken it for granted that a person prefers one thing to another if and only if it gives him/her more well-being. This view may be called *preferencism*. On the face of it, preferencism is implausible. For example, presumably a person might altruistically prefer one thing to another because it is better for someone else, even if it brings himself/herself less well-being. The ordinalist espoused the doctrine of *operationalism*. According to operationalism, the meaning of a concept such as well-being is given by the operations we use in order to apply it. The ordinalists recognized no operation that would allow us to apply the concept of well-being except the operation of observing people's preferences. They thought that the only meaning well-being can have is given by the preferencist formula. This means that utility measures well-being in an ordinal way: higher utility indicates higher well-being. The order of well-being – whether one thing is better or worse for a person than another – therefore counted as a scientific concept, but the ordinalists acknowledged no other aspect of well-being. Well-being could not be counted as an arithmetic quantity, nor could differences of well-being be compared between people. The preconditions of precise utilitarianism could therefore not be met.

Nevertheless, the ordinalists were utilitarian at heart. Consequently, they clung to the flimsy remnant of utilitarianism that survived their epistemic censure. They accepted the *Pareto criterion*, named in honor of Vilfredo Pareto (1927). The Pareto criterion says that one state of affairs is better than another if everyone either prefers the first to the second or is indifferent between them, and if someone strictly prefers the first. This sufficient condition for one alternative to be better than another was the sole evaluative principle that the ordinalists were prepared to recognize. Few pairs of alternatives satisfy this condition, so shrinking utilitarianism to the Pareto criterion cripples it. Ordinalism stultified welfare economics for decades. In particular, it denied that any judgment could be made about the value of equality.

A possible escape from the ordinalist straightjacket seemed to be offered by expected utility theory. Because this theory yields cardinal utility functions, some authors thought it might allow well-being to be measured cardinally. However, this thinking was confused about the relation between utility and well-being. Granted preferencism, utility measures well-being ordinally. Even granted preferencism and granted also that cardinal utility can be defined within expected utility theory, it does not follow that this cardinal utility measures well-being cardinally. Differences in utility are comparable, but it does not follow that they represent comparable differences in well-being.

Furthermore, the second condition of precise utilitarianism remains unsatisfied. Nothing in expected utility theory makes one person's well-being comparable with another's.

Nevertheless, John Harsanyi in the 1950s produced no less than two new and important arguments that were intended to show that, indeed, the cardinal utilities defined by expected utility theory do have a place in ethical judgments.

His first argument (Harsanyi, 1953) was this. Suppose we are comparing societies, asking which the best is. Harsanyi argued that this question could be answered by imagining a person who is allowed to choose among the different societies. He/she knows that he/she will become a member of the one he/she chooses but does not know which position he/she will occupy within it. He/she has an equal chance of finding the best position, or the worst, or anywhere else. Harsanyi claimed that the best society is whichever one he/she would choose under these circumstances. This is an appeal to the idea of a 'veil of ignorance,' which was later taken up by John Rawls (1972).

From the person's point of view, he/she is choosing between acts whose results are uncertain: the result of choosing a particular society will be that he/she ends up in an unknown position within that society. According to expected utility theory, for this person there will be a utility assigned to each position in the society, and the utility for him/her of entering the society will be the average of all these individual utilities. Therefore, of the alternative societies available, the person will choose the one that has the greatest average utility. If we assume every society has the same population, this is also the one that has the greatest total utility. According to Harsanyi, then, the best society is the one with the greatest total utility. This argument does indeed give a place in ethical judgments to utility as expected utility theory defines it.

Does it also support utilitarianism? Precise utilitarianism implies that the best society is the one with the greatest total of well-being. Therefore, if utility measures well-being cardinally, Harsanyi's conclusion resembles precise utilitarianism. However, Harsanyi's argument falls short of a complete argument for utilitarianism, because we still have no reason to think utility does measure well-being cardinally. Furthermore, the problem of comparing one person's well-being with another's remains.

Harsanyi's second argument (1955) was a formal theorem that is too complex to describe here. It is entirely distinct from the first argument, and it does not rely on a veil of ignorance. Still, it arrives at a similar conclusion, that the best society is the one with the greatest total of people's utility. For the same reasons as before, it does not amount to a complete defense of utilitarianism. Nevertheless, Harsanyi's two arguments cast an important new light on utilitarianism, and went a long way toward providing it with completely new foundations.

These foundations are based on preferences, and they depend on preferencism. Within moral philosophy as well as economics, it has become increasingly popular in recent years to base utilitarianism on preferences rather than, say, pleasure and pain. One reason is the prestige given to preference-based utilitarianism by Harsanyi's impressive work. His work issued, in turn, from the dramatic revision of utility theory caused by ordinalism. These are examples of the strong influence that economics has had on utilitarian thought.

Tools for Ethics

Economists have developed for their own purposes various formal tools that also turn out to be useful in ethics. Utility theory is one: apart from its contribution to utilitarian thought, it has other significant applications within ethics. For one thing, it constitutes a partial account of practical rationality; it specifies what rationality requires of a person's preferences. An account of practical rationality is an essential background to ethical theory. For another thing, utility theory can easily be converted from a theory of preferences to a formal theory of the structure of value, by applying its axioms to *betterness* instead of preferences (Broome, 1991).

Game theory is a second prominent example of a tool useful in ethics. The *prisoners' dilemma* (qv) and related 'games' have led to some radical rethinking of the nature of rationality. Some authors (e.g., Gauthier, 1985) have argued that they call for an understanding of individual rationality that somehow embodies an ethic of cooperation. *Bargaining theory*, too – a branch of game theory – has proved useful at the foundations of contractualism (qv) (see Gauthier, 1985; Binmore, 1994 and 1998).

A third example is *social choice theory*. Social choice theory is a branch of welfare economics that is principally concerned with *aggregation*. It examines how the interests of individuals are aggregated together to determine the overall goodness of a society. One example of a principle of aggregation is the utilitarian principle that overall goodness is the arithmetic total of people's well-being.

Social choice theory originated in Kenneth Arrow's *Social Choice and Individual Values*, published in 1951 (*see* Arrow, 1951). As an ordinalist, Arrow was concerned with aggregating specifically preferences. His conclusion was negative; he demonstrated that people's preferences cannot generally be aggregated together in a plausible way to determine an overall ordering of the alternatives, ranking them from best to worst.

As a result, since Arrow's time, social choice theorists have gone beyond the bounds of ordinalism. They are no longer concerned with aggregating preferences only. A leader in this movement is Amartya Sen (1970), whose *Collective Choice and Social Welfare* both codified social choice theory and set the scene for this new departure. Ordinalism combined a utilitarian concern for people's well-being with skepticism about a quantitative notion of good. One can give up the skepticism, and many economists nowadays unashamedly take for granted a quantitative notion of a person's good or well-being. Alternatively, one can give up the utilitarianism and focus concern on something that is less prone to skepticism. Sen (1987) himself focuses on people's *capabilities*, by which he means the collection of things that they are enabled to do by the resources at their disposal.

A new application for social choice theory has emerged in the philosophical discussion of 'moral uncertainty.' Moral philosophy is full of debate, disagreement, and uncertainty. Often a person or a government needs to make a decision among alternatives that raise moral issues, but where it is uncertain what the right moral principles to apply are. Each moral theory will rank the various alternatives, and different theories may well rank them differently. The decision has to be made somehow on the basis of these conflicting moral

considerations. How should one act when it is uncertain how one should act? That is the problem of moral uncertainty (Sepielli, 2009).

It is closely analogous to social choice theory. Each separate moral theory is analogous to an individual person. A theory's ranking of the alternatives is analogous to a person's ranking of alternatives, by his/her preferences or by some other criterion. The different theories' rankings have to be aggregated somehow to determine a choice, just as individual people's rankings have to be aggregated somehow to determine a social choice. Therefore, social choice theory can make a useful contribution to the philosophy of moral uncertainty.

Shared Topics

Economists and moral philosophers share an interest in several specific, practical subjects, but the cooperation between the disciplines in dealing with them is weaker than it should be. This section mentions two examples.

The Value of Life

For practical purposes, welfare economists are faced with the need to set a value on people's lives. For example, railways can be made safer by spending money on them. One benefit of doing so will be that fewer people are killed in train accidents. Economists need to decide how much money is worth spending to achieve this benefit. They need to determine how much good is done by saving a person's life or, equivalently, how much harm is done by a person's death. For another example, some very expensive drugs can extend a person's life for a few months. Is the benefit worth the cost?

Since ancient times, philosophers, too, have been interested in the value of life. Some modern discussion (e.g., Nagel, 1979; Feldman, 1991) has been stimulated by an argument of Epicurus (1926). Epicurus tried to show that death is harmless to the person who dies, and the modern issue is still whether death is an evil and whether life has value. Some other modern philosophical writing takes it for granted that life is valuable, and asks more quantitative questions. For example, one issue that has been discussed is whether the value of a life is more affected by events that happen later in life or by those that happen earlier (e.g., Velleman, 1991).

Much of the philosophical discussion is about the aggregation of a person's good over the lifetime. How so the good things that come to a person at different times in life come together to determine the goodness of life as a whole? The formal techniques for aggregation within economics can make an important contribution to the philosophical discussion. Conversely, the evaluation of life within economics clearly calls out for philosophical assessment. There has been some contact between the disciplines in this area (e.g., Broome, 2004), but there is room for much more.

Equality

For a long time, welfare economists have been concerned with the value of economic equality; examples of important contributions are by Atkinson (1970) and Sen (1973). The same subject has also recently become important in moral philosophy; leading works are by Parfit (1991) and Temkin (1993). In this area, too, contact between philosophers and economists has been limited, and both disciplines would benefit greatly from more.

The philosophers can fairly be said to have discovered an important distinction. Two very different moral concerns can have similar practical consequences. One – generally called *prioritarianism* – gives more importance ('priority') to improving the well-being of badly off people than to improving the well-being of well-off people. Prioritarianism will generally lead one to steer resources toward worse-off people, which will generally have the effect of promoting equality. However, equality is not its direct object. A different concern is simply to reduce the gap between the better-off and the worse-off; this is sometimes simply called *egalitarianism*.

The distinction is genuine, but because their effects are similar, it is difficult to specify the precise difference between prioritarianism and egalitarianism. The formal methods of economics have the resources to do so. Indeed, the economic literature on inequality implicitly contains detailed analyses of both concerns. Despite that, the distinction has not been clearly recognized in economics; it is something that economics needs to learn from philosophy. Conversely, all the formal analysis that is already available within economics could help philosophers clarify the distinction they are making and better understand its consequences. On the subject of equality, more cooperation would be very fruitful.

To summarize, economics and ethics have learned a great deal from each other, but they could learn a great deal more.

Abstract

Economic thought can be found in the early literature of every civilization. However, an economics discipline emerged only in the sixteenth, seventeenth, and eighteenth centuries in Western Europe. The outlines of orthodox modern economics appeared after the Marginal Revolution of the 1870s. Strands of heterodox economics took root soon after: macroeconomics, institutional economics, and Marxian economics. Study of the history of economics began in the eighteenth century as a way of dismissing or celebrating ancestors. In the twentieth century, major contributors to economics turned to history for the 'extended present' of their inquiry. In the second half of the twentieth century, economists turned away from their history because the opportunity cost of teaching and research seemed too great. In response, specialists established their own journals and societies and emphasized the teaching of undergraduates. In the twenty-first century, stimulating research has kept the history of economics vigorous and alive. Crises in economic affairs have turned some economists back in time to seek explanations. Challenges that remain for historians of economics include where to find a happy home in the academic landscape and where to conduct postgraduate training.

The History in a Nutshell

The roots of the subject that we know today as economics go back at least to the classical Greeks several hundred years before Christ, and economic ideas can be found in early Chinese, Indian, Islamic, and other non-Western literatures as well (Lowry, 1987). It is apparent that humans cannot engage in economic activity without at the same time reflecting upon it. These early economic ideas were usually embedded in other bodies of thought such as philosophy and theology and advocacy for particular policies or institutions. A discipline of economics did not take shape until the eighteenth century and a profession by which scholars could make a living did not appear until later still. Early thinking about economic questions typically centered on price determination and especially the impact of monopoly on markets. Scholars looked at the distribution of income and wealth, taxation, the role of government, and the functions of money. Influential thinkers in this prehistory of economics included the Greeks, notably Plato (*c*.427–347 BC) who proposed a model of an ideal economy, Aristotle (384–322 BC) who attempted to determine justice in an economic system, and Xenophon (*c*.430–355 BC) who proposed economic policies for the state and rules to govern public expenditures. Christian scripture in the Bible and writings of the early church fathers attempted to reconcile economic activity as it was evolving with their religious doctrine. During the Middle Ages, churchmen such as St Thomas Aquinas (AD 1225–74) and members of the School of Salamanca in the sixteenth century addressed economic questions that arose in the feudal system and especially in markets that so often were imperfect because of their relative isolation (Monroe, 1924).

A body of ideas that looked like what we call today economics began to emerge in the sixteenth, seventeenth, and eighteenth centuries, stimulated by the extension of world trade, the growth of national states, the use of money as the means of exchange, the scientific revolution, and the Renaissance in knowledge overall (Backhouse, 2002). Questions surrounding the functions of money and the conduct of trade became highly contentious and stimulated serious reflection from profound thinkers, for example, Jean Bodin (1530–96), William Petty (1623–87), and John Locke (1632–1704). These protoeconomists began and engaged vigorously in some of the first extended controversies over such issues as the case for colonies, protection of certain industries and trades, and responsibilities of the state for banking and currency. Participants in the extension of international commerce such as Thomas Mun and Dudley North combined curiosity about the process of which they were a part with a desire to influence affairs for their own benefit. During the eighteenth century, Enlightenment thinking that spread across Europe led to the first well-rounded and coherent bodies of economic thought that came to be called political economy (later classical economics), and were supported by enthusiastic groups of followers identified sometimes as 'schools.' These political economists attempted to explain economic phenomena by reference to systems of theory particular to their schools. The new subject flourished especially in France in the works of Richard Cantillon, Anne Robert Jacques Turgot, and Francois Quesnay; in Scotland in the writings of David Hume, Adam Smith, and James Steuart; and in Italy with Ferdinand Galiani. In most cases, political economy at this time emerged from and remained close to moral philosophy, and gained strength from the study of history and science and the general intellectual ferment of the times (Hollander, 1987). In the nineteenth century, classical economics was extended and developed by Thomas Robert Malthus, David Ricardo, Jeremy Bentham, Karl Marx, J.B. Say, John Stuart Mill, and many others. Subfields appeared that covered money and banking, international trade, colonization, and other specialized topics. Political economy was introduced somewhat hesitantly into the curricula of universities across Europe.

Most economists today might conclude that modern economics began only with what is now called 'neoclassical' economics, a body of thought that emerged in several countries more or less independently and expanded rapidly in four countries: England (William Stanley Jevons, Alfred Marshall, and Francis Edgeworth), France (Leon Walras), Austria (Carl

Menger), and the United States (John Bates Clark and Irving Fisher). The economics of each of the neoclassical pioneers had distinctive characteristics, but overall they shared at least two features. First, they emphasized the actions of individuals operating independently in markets as buyers and sellers while pursuing their perceived welfare, either profit for business people or 'utility' for consumers as it was called by some. Second, the behavior of these participants in the economy was described more and more by the neoclassicals using mathematical tools, beginning with simple algebra and the calculus (Black et al., 1973). This approach was intended to give greater rigor to the subject and to move it more and more into the category of 'science,' away from moral philosophy and psychology. Some of the main early critics of classical and neoclassical economics were economic historians centered in Germany (Wilhelm Roscher and Gustav Schmoller) and Great Britain (T.E. Cliffe Leslie and William Ashley) who questioned the use of abstraction to understand human behavior, and moral critics like Charles Dickens, John Ruskin, and Anthony Trollope who disputed the social consequences of competitive market activity (Tribe, 1995; Koot, 1987). They described in graphic detail what might be called today negative externalities of market phenomena.

In the twentieth century, with a steadily increasing number of economists entering the field, and the subject gaining acceptance as a respected discipline in the academy, the history of economics becomes more complex. Neoclassical theory was increasingly more technical with important additions like general equilibrium theory and the theory of games. The new field of econometrics used statistics to test, apply, and extend economic theory. Additional applied subfields of economics took shape such as public economics, industrial organization, law and economics, and labor economics. More specialized fields also appeared, concerned with such topics as health, the environment, and education. Increasingly, economics was carried beyond faculties of arts and sciences of colleges and universities where it first took root, into schools of business, law, agriculture, natural resources, public policy, and beyond. Economic reasoning was applied also with increasing frequency in such fields as political science and sociology. All of these engagements of economists with a myriad of new questions and new institutions, often with distinctive national perspectives, enriched and complicated the history of the subject.

Beyond the extension of neoclassical economics in the twentieth century, three strands of heterodox economics attracted economists to their banners. Stimulated by increasingly severe business cycles and depressions, beginning in the 1890s and reaching a peak in the 1930s, some economists using their new tools of analysis began to question the automaticity of a free market system and wondered whether the state had a responsibility to intervene in recessions and pay attention to such large aggregates as employment, production, price levels, and growth rates. Early macroeconomists, as they came to be called, like John Hobson in Britain, did not receive much attention, but John Maynard Keynes with his *General Theory of Employment, Interest and Money* (1936) was revolutionary (Backhouse and Bateman, 2006). This work challenged the discipline, affected public policy, and has remained a subject of controversy into the twenty-first century. In addition to suggesting new perspectives on the economy and new tools of analysis, Keynes argued that economists needed to address more fully certain variables like human behavior that had been set aside in neoclassical economics. He also provided the basis for optimism among those economists who before had viewed the tragedy of the Great Depression with resignation and almost with despair. Keynes's disciples included some of the most distinguished economists of the second half of the twentieth century, such as Joan Robinson, Richard Kahn, Paul Samuelson, and James Tobin, and the entry of his ideas into public policy constitutes some of the most fascinating history of economics in action. Keynes was an economist with an exciting personal life, both outside and inside the academy, in business and the arts (Skidelsky, 1983). He has seldom failed to intrigue historians of the twentieth and twenty-first centuries.

The second element of heterodox economics, or at least economics, that was different from the neoclassical mainstream, appeared in the United States in the late nineteenth century and flourished into the second half of the twentieth century. Practitioners were usually well trained in conventional neoclassical theory, but whether through experience in their new country or training in the historical tradition in Germany they were dissatisfied with received doctrine. In some cases under the influence of Thorstein Veblen, the pioneer in this tradition, they viewed the economy as made up of biological organisms, constantly evolving as Darwin had explained (Veblen, 2007). The metaphor for the economy that appealed to them was a community of complex, ever-changing individuals usually in disequilibrium rather than moving toward equilibrium in the mechanical clock metaphor preferred by some neoclassicists. The disciplinary boundaries of this American evolutionary or institutional economics were much wider than the neoclassical ones, encompassing history, anthropology, sociology, psychology, and even literature and the arts (Rutherford, 2011). A high premium was placed on the accumulation of data, the study of history, and a focus on public policy problems. They were quite ready to contemplate interference with markets, and the policy implications of this new approach often fitted well with the Progressives who emerged as a strong force in American politics early in the twentieth century. Several venerable structures in American professional economics can trace their origins to the institutionalists, notably the National Bureau of Economic Research and the Brookings Institution.

The third type of heterodox economics that challenged neoclassical economics grew out of the work of Karl Marx, both his incendiary *The Communist Manifesto* (1848) with Friedrich Engels and his major work in political economy *Capital* (1867, 1885, and 1894). This strand had a good deal in common with that of the historical economists and the American institutionalists (Howard and King, 1975). In particular, all three saw the participants in the economy as complex, evolving creatures, which could not be understood through neoclassical models alone that assumed merely profit-maximizing and utility-maximizing behavior. But Marxian economics was more than an analytical system. It was also a call to arms to improve a world in which 'contradictions of capitalism' steadily were becoming more severe and through a dialectical process would

sooner or later precipitate revolutionary change. Like the other strands of heterodox economics, Marxian doctrine connected with various disciplines like history and philosophy from which it drew strength.

Why Should Anyone Become Engaged with the History of Economics? And Why Not?

Why has anyone bothered to explore and explain the history of economics? One obvious answer is because they have been intrigued by questions of how the modern discipline has come to its current condition. This curiosity increased as economics has taken on importance in national life. But there are other reasons. Many of the earliest economists looked back into the history of their subject to make the case for their own priority in it. Some denigrated their predecessors to strengthen the case for their own ascendance. In this spirit, the mercantilists described and criticized the work of the church fathers. The classicals attacked the mercantilists. Others applauded their forebears. The neoclassicals, and especially William Stanley Jevons and Irving Fisher, searched for pioneering predecessors, such as Augustin Cournot, to compare favorably with such prominent contemporary classicists as John Elliot Cairnes and John Stuart Mill. Similarly, John Maynard Keynes looked for sympathetic ancestors to support the virtues of his 'new' economics. He attacked David Ricardo for his kind of theorizing and praised Thomas Robert Malthus for anticipating some of his ideas. The American institutionalists Thorstein Veblen and John Kenneth Galbraith condemned the entire neoclassical project. There were few scholars before the twentieth century who examined the history of economics for its own sake. One exception was the Scottish scholar-journalist J.R. McCulloch (1845).

It was customary for economists in the early twentieth century to include some history of the theoretical or empirical work on which they were engaged in lectures or publications on the ground that economics had what Kenneth Boulding called 'an extended present.' Claims made about a subject of contemporary interest several decades before, it was thought, were likely to remain unsettled and therefore of legitimate current interest. This view of the study of the history of economics as a legitimate part of current inquiry was given a fillip in the first half of the twentieth century by several leaders in economics who included substantial historical components alongside their work on theory or policy. These include, among others, Joseph Schumpeter (*History of Economic Analysis*, 1954), Jacob Viner (*Studies in the Theory of International Trade*, 1937), Lionel Robbins (*The Theory of Economic Policy in Classical Political Economy*, 1978), George Stigler (*A History of Production and Distribution Theories*, 1941), and Joseph Spengler (*French Predecessors of Malthus*, 1942). The history of economics at this time consisted mainly of careful readings of historical texts and explanation of what these early authors meant as seen through the eyes of a modern economist. These works contained impressive historical scholarship by authors of unquestioned prominence who were known primarily for their theoretical or applied work but who found that the history of economics was relevant to their current concerns. Another argument for the 'extended present' view of the history of economics was that without it economists were likely to reinvent the wheel or commit errors that had been corrected long since. With so many historical monographs of this type being published well into the second half of the twentieth century, little need was perceived for conventional textbooks in the history of economics and the few that were used widely, such as those by Charles Gide and Charles Rist (1948) and by Alexander Gray (1931), were in print for a long time.

A marked turning away from the history of economics as a distinct subject within the economics discipline occurred during the second half of the twentieth century, especially in the United States, which by this time had come to dominate the profession globally. Separate courses in the subject were discontinued at the postgraduate level, especially in North American PhD programs. The premier journals in economics declined any more to publish, or even to review, manuscripts on the history of the field, except for the *Journal of Economic Literature* and the *Journal of Economic Perspectives*, which were aimed at recent history. The national meetings of economists had fewer and fewer sessions dealing with the history of economics and few job openings were posted. Various reasons have been suggested for this decline of interest and attention. One is that with the increasing sophistication of the theoretical core of economics more teaching time was needed there. Another is that relatively new specialties like econometrics made a strong case for more teaching space, and consequently the opportunity cost of teaching history steadily rose. But perhaps the most important reason for the decline of history is that after World War II, in which economics made a valued contribution to the War effort, the discipline attempted strenuously to define itself once and for all as a real hard science and not a literary subject. One triumphant accomplishment was to be included within the new National Science Foundation rather than the National Endowment for the Humanities. Another was to be included among the Nobel Prizes in 1968 with a prize given by the Bank of Sweden in memory of Alfred Nobel. Leaders of the economics discipline apparently came to believe that the nature of science was to retain in the current literature all that was 'true' and to discard all that was 'false.' By this reasoning, any interest in the history of science was either redundant or antiquarian, and historical study had no claim on scarce appointments, research funds, space in publications, or teaching time. What had been sophisticated historical introductions in classes and publications were gradually replaced by 'literature reviews' of current material. What came to pass for history in the higher reaches of the discipline after this was often little more than hagiographic celebration of prominent figures of the past and present.

Yet, despite this loss of respect within the mother discipline, the history of economics as a field did not go away and die. In fact, quite the opposite, in many respects it grew and prospered. During the 1960s and 1970s, as history was purged from the mainstream of the discipline it found new life on its own. Specialized international journals sprang up, the first being *History of Political Economy*, followed by the *Journal of the History of Economic Thought*, the *European Journal of the History of Economic Thought*, *History of Economic Ideas*, and *Research in the History of Economics Thought and Methodology*. Professional societies were established in North America, Europe, and some individual countries including France, Japan, Australia, and

Italy. Country-specific journals were started, connected in most cases with the national societies: *History of Economics Review* (Australia), *Cahiers d'economie politique* (France), *Storia del pensiero* (Italy), *The History of Economic Thought* (Japan), and others. A number of valuable resources became available on the Internet including the Economic Research Network's *History of Economics Journal* and *Weboeconomia*. A *Guide to Archival Sources for British and Irish Economists*, supported by the Royal Economic Society, was published in the 1970s.

Paradoxically, within a few decades of the history of economics being removed from the curricula of many colleges and universities, meetings of the international societies that sprang up in response were attracting several hundred attendees. By the 1990s, the annual meetings of the American Economic Association began again to include sessions on history arranged by and in association with the History of Economics Society. While the teaching of the history of economics virtually disappeared at the graduate level in the United States, it increased among undergraduates, especially at liberal arts colleges and less prominent universities. Textbooks to satisfy all ideologies and teaching styles were published. The most notable was Mark Blaug's *Economic Theory in Retrospect* (1962), which was applauded by some because it interpreted and judged early works through modern eyes, and was criticized by others because of its 'Whig' bias of appraising historical contributions according to their congruence with modern theory. Other influential early textbooks in the years when the history of economics struck off on its own included Henry Spiegel's *The Growth of Economic Thought* (1983) and Robert Heilbroner's *The Worldly Philosophers* (1953). Perhaps upward of a thousand scholars worldwide by the end of the twentieth century would admit to being serious students of the field.

To supplement the vigorous institutional response to the abandonment of the history of economics by the economics discipline in the 1960s, there was an intellectual response that stimulated research in the subject. In part because of the loss of firm leadership of the subject by prominent historian-theorists the subject was opened up to new approaches and new hypotheses. From the history and philosophy of science came the theory of scientific revolutions of Thomas Kuhn (1970) and the scientific research programs of Imre Lakatos (Lakatos and Musgrave, 1970). From philosophy came the complex analytical perspective of Michel Foucault and from the economic historian Donald McCloskey the conception of economics as a conversation and the exercise of rhetoric (McCloskey, 1985). Philip Mirowski introduced a controversial interpretation of the marginal revolution that suggested much of the economic theory of the time was borrowed from contemporary physics (1989). Judy Klein, Mary Morgan, and others recorded the close relationship between the development of economics and World War II, especially in research institutions like the RAND Corporation, the Cowles Commission, and the Brookings Institution (Klein and Morgan, 2001). E. Roy Weintraub described the mathematization and formalization of the subject in the twentieth century (2002). The study of economic methodology and the philosophy of economics that had its roots in the history of the subject moved out on its own with separate journals and fields. All of these approaches stimulated research projects and conferences to explore more widely the applicability of the new analytical perspectives to economics.

What sustains this interest in the history of economics after the setbacks of the mid-twentieth century? Several answers to this question can be suggested. Despite the decline in teaching at the graduate level, the history of economics as a distinct subject continues to appeal to undergraduates precisely because they have not been provided the kind of background that typically was used to introduce courses 50 years ago. Where did these tools and models come from, they ask, and are there alternatives to them? Why did the dominant theory triumph? How is modern economics used in our society? What is the relationship between the classroom and the real world? What questions are answered unambiguously and which ones remain in dispute? An explanation for the continuing flow of research and publications in the history of economics is more complex. Some faculty members have moved into historical studies from various other subfields of economics because they have been alienated by the level of abstraction in economics or by the ideological overlay that they perceive in the discipline, which makes them uncomfortable. Both students and faculty find in the history of economics the opportunity to maintain respectable continuing contacts with heterodox traditions that are not always tolerated by the mainstream. For example, both Austrian and Marxist economists are well represented in the history of economics. Opportunities for interdisciplinary adventures also abound in the history of economics, with scholars in the humanities and the arts as well as with the other social sciences, and this pleases college administrators as well as teachers and students. Answers to questions are seldom provided unambiguously and answered conclusively in the history of economics, and so there are ample opportunities for vigorous discussion, creative writing, and debate by students and faculty, a style of inquiry often unwelcome in the modern economics discipline.

The History of Economics in the Twenty-First Century

There are reasons for optimism and also for unease about the future of the history of economics in the twenty-first century. On the positive side the Great Recession that began in 2007 gave a notable boost to the subject. Doctrines that had been perceived by some to be settled verities suddenly were brought into question. Do financial markets really correct themselves on their own after a crisis like the mortgage meltdown as competitive market theory suggests? What can earlier explanations of financial turmoil contribute? Has Keynesian economics been discredited after all? Or Alvin Hansen's stagnation thesis? What did Hayek actually say? If welfare provisions are truly in peril did the fault lie to some degree in the doctrine from which they sprang? If new global policies and institutions are required to restore prosperity what could we learn from the theory that underlay the old structures? Both teaching and research in the history of economics were stimulated by these questions and others like them. The answers to many of the questions clearly demanded attention to history, and it was discovered that history could be a liberating force to think new thoughts. Approaches taken to questions in the history of economics over the last decades have been more diverse than the traditional approach of careful and reverent exegesis of economists' texts, which was the standard approach

through the 1960s. Recently, attention has been paid to the activities of departments of economics, rather than simply prominent individuals (notably, departments at the University of Chicago and MIT), other creative communities of various kinds, and schools of thought like the Austrians, the Keynesians, and the American institutionalists. New opportunities for research with this greater breadth have been provided by collections of papers and manuscripts of economists increasingly made available in university libraries such as those of Columbia, Chicago, Harvard, Duke (the Economists' Papers Project), and Stanford (Hoover Institution), as well as in the Presidential Libraries of the National Archives and Records Service. The improved availability of economists' papers must be balanced by the reality that in the twenty-first century many records of correspondence, reading notes, drafts of research results, and other materials are in electronic form and may be lost to scholars when they are deleted. More and more of the collected published writings and letters of major economists are being carefully edited and published (e.g., *The Collected Works of Friedrich Hayek* and the letters of Dennis Robertson, both in progress in 2014). Interpretive biographies have provided increased understanding of major figures such as Keynes (by Donald Moggridge, 1992; Robert Skidelsky, 1983), Harry Johnson (Moggridge, 2008), Friedrich Hayek (Bruce Caldwell, 2004), and Lionel Robbins (Susan Howson, 2011). For the first time some funding sources have given priority to the history of economics as an entry point to the broader discipline. Examples are the Institute for New Economic Thinking, supported by George Soros, and the National Endowment for the Humanities.

New vigor has been added to the history of economics in the twenty-first century also by arrival in the field of scholars from other disciplines who might have perceived barriers to entry in the twentieth century but now are warmly welcomed. Examples include the intellectual historians Michael Bernstein whose *A Perilous Progress: Economists and Public Purpose in Twentieth-Century America* (2001) described economists in the policy sphere, and Angus Burgin whose *The Great Persuasion: Reinventing Free Markets since the Depression* records economists in the growth of the neoliberal tradition. From the history of science, Mary Morgan (2012) has examined the economist's use of models and with Harro Maas has made use of the 'witness seminar' as an historical technique (2012). The sociologist Marion Fourcade has compared the growth of professional traditions among economists in several countries (2009).

The challenges facing historians of economics in the twenty-first century are fully as substantial as the opportunities. The first challenge is to establish where the subject may settle in the academic landscape. At present, most of the historians rest somewhat uncomfortably in second-tier economics departments and more comfortably in liberal arts colleges, earning their keep for the most part by teaching courses in conventional economics subjects in which they have been trained, but perceived by their economist colleagues, who by this date have been exposed to little history, as puzzling anomalies seemingly unrelated to the main purposes of an economics department. It has been suggested that historians of economics might better migrate to history, philosophy, or history of science departments, but most wish not to do so as they think of themselves as economists; in any event, it is doubtful that they would find a warm welcome in these other departments that are themselves frequently under stress in their college and university homes. The continued welcome to historians of economics in economics departments is likely to depend on their continued ability to attract good undergraduate students to their classes and to offer an appealing curriculum whose opportunity cost is not too high. A particular threat to the survival of historians in economics departments, especially outside the United States, is the practice by rating agencies of appraising departments by the volume of their research output and then classifying publications by historians of economics as history rather than economics.

A deeper challenge to the survival of the history of economics in its current place and its current form is the almost total withering away of postgraduate training in the field. Here and there a course is offered still at the graduate level, but nowhere is there a dedicated PhD program. This means that virtually all of the new entrants to the field must move laterally from some other discipline or some other specialty in economics and without any special training in historical methods or other tools of the trade such as oral history or use of archives. An effort is being made at Duke University to revive doctoral training as part of the activities of the Center for the History of Political Economy, and there are also hopeful reports of graduate students at several universities requesting the reinstatement of history courses.

Abstract

Economics is of philosophical interest for three reasons. First, its methodological peculiarities: its extreme simplifications, its inexactness, its reliance on a deductive method, and the importance of causal claims concerning mechanisms, tendencies and capacities. Second, economics depends on a theory of rationality and has implications for the understanding of preference, utility, and self-interest. Finally, economics is relevant to ethical questions, particularly concerning efficiency and welfare. Philosophical reflection is of interest to economists because it can help to clarify methodological problems, improve the theory of rationality, and unscramble, expand, and sharpen the ethical implications. Although the philosophy of economics addresses many topics, a great deal of it has focused on the specific model of rationality and choice that is embedded in mainstream microeconomics. But the failure of economists to anticipate the financial crisis of 2008 and to provide unambiguous advice about how to restore prosperity has increased interest in the methodology of macroeconomics.

Like many of the social sciences, economics grew out of philosophy, and the concerns of economists continue to intersect with those of philosophers. Philosophical reflections on (1) scientific method and social ontology; (2) the nature of rationality, self-interest, and preference; and (3) welfare, justice, equality, and freedom are of abiding significance to economists and other social scientists.

Economic Methodology

Philosophical reflection on economics is ancient, but the conception of 'the economy' as a distinct object of study dates back only to the eighteenth century. Aristotle addresses problems of economics mainly as problems of household management. Scholastic philosophers addressed ethical questions concerning economic behavior, and they condemned 'usury' – that is, the taking of interest on money. With the increasing importance of trade among nation-states in the early modern period, 'mercantilist' philosophers and pamphleteers addressed questions concerning the balance of trade and the regulation of the currency. Only in the work of the physiocrats and especially of Adam Smith did scholars begin to think of the economy as an object of study with its own principles and laws.

Eighteenth century philosophers wrote in the shadow of Newton's towering accomplishments. David Hume is unabashed about his hopes to develop a science of mind and society in the image of Newton's science of the solar system. To that end, he seeks out general laws of individual thought and action, out of which larger-scale orderly relations will arise, in just the way that patterns in planetary motion arise from the laws of motion and gravitation governing individual bodies. Thus Hume traces the rise in prices and the temporary increase in economic activity that follow an increase in currency to the perceptions and actions of individuals who first spend the additional currency.

It then lay to Adam Smith to extend such a method to his systematic *Inquiry into the Nature and Causes of the Wealth of Nations* (1776) and to make explicit an implication of previous causal inquiries such as those of Hume, the physiocrats, and of many of the mercantilists. That implication (which is arguably the foundation for all social science) is that the social, aggregative implications of individual choices are often *unintended*. In spending their additional gold imported from abroad, traders do not intend to increase the price level. But that is what they do nevertheless. Unintended regularities that arise from the intentional choices of individuals can rule those individuals just as surely as the regularities of nature, and, like nature, societies can be objects of scientific investigation.

Classical Economics and the Method a priori

Adam Smith wrote little explicitly about the method of economics. The first extended reflections on economic methodology had to wait until Nassau Senior (1836) and John Stuart Mill (1836). Their essays must be understood against the background of the prevailing economic theory. Like Smith's economics (to which it owed a great deal) and modern economics, the 'classical' economics of the middle decades of the nineteenth century traced economic regularities to the choices of individuals facing social and natural constraints. But, as compared to Smith, economists relied more heavily on severely simplified models. David Ricardo's *Principles of Political Economy* (1819) depicts a society in which wages above the subsistence level lead to an expanding labor force, which in turn requires more intensive agriculture or cultivation of inferior land. The extension of cultivation leads to lower profits and higher rents. Economic development leads to a gloomy stationary state in which profits are too low to command any net investment, wages return to subsistence levels, and only the landlords are affluent. The data available to classical economists were never in accordance with the trends that the theory predicted. Yet the theory continued to hold sway for more than half a century, and the unfavorable data were explained away as due to 'disturbing causes.'

It is not surprising that Mill's account of the method of economics would emphasize the relative autonomy of the theory. Mill distinguishes two kinds of inductive methods. The method a posteriori is a method of *direct* experience. It is only suitable for phenomena in which few causal factors are operating or in which experimental controls are possible. Mill's famous methods of induction are detailed specifications of the

method a posteriori. In his method of difference, for example, one holds fixed every causal factor except one and checks to see whether the effect ceases to obtain when that one factor is removed.

Mill argues that direct inductive methods cannot be used to study phenomena in which many causal factors are in play. If, for example, economists attempt to investigate whether tariffs enhance or impede prosperity by comparing the prosperity with and without tariffs, the results will be irregular and unreliable because other causes besides tariffs will also differ across societies and times. So economists need instead to employ the method a priori. Despite its name, this is an *inductive* method, but it is an indirect inductive method. In Mill's view, scientists first determine the laws governing individual causal factors in domains in which direct inductive methods are applicable. Having then determined the laws of the individual causes, scientists investigate their combined consequences deductively. Finally, there is a role for 'verification' of the combined consequences, but owing to the causal complications, the testing of the conclusions serves only as a check on the deductions and as an indicator of whether there are significant disturbing causes that scientists have not yet accounted for. Mill gives the example of the science of the tides. Physicists determine the law of gravitation by studying planetary motion, in which gravity is the only significant causal factor. Then they develop the theory of tides deductively from that law and information concerning the positions and motions of the moon and sun. The implications of the theory will be inexact and sometimes badly mistaken, because many subsidiary causal factors influence tides. By testing the theory, scientists can uncover mistakes in their deductions and evidence concerning the role of the subsidiary factors. Because of the causal complexity, such testing does little to confirm or disconfirm the law of gravitation, which has already been established.

Because economic theory includes only the most important causes and necessarily ignores many minor causes, its claims, like claims concerning tides, are inexact. Its predictions are imprecise, and sometimes dead wrong. But it is possible nevertheless to develop and confirm economic theory by first establishing in simpler domains the laws governing the major causal factors and then deducing their combined consequences in different circumstances. For example, statistical data tell a mixed story about the relationship between minimum wages and unemployment; and there are no data concerning the consequences for employment of an extremely high minimum wage. On the other hand, everyday experience teaches economists that firms can choose among more or less labor-intensive processes and that a high minimum wage will make more labor-intensive processes more expensive. Since economists also have good reason to believe that firms try to keep their costs down, they have good reason to believe that a high minimum wage will increase unemployment.

According to Mill, economics is not only inexact and committed to the method a priori. In addition, he maintains that it is a *separate science*. What distinguishes economics as a discipline is both its concern for a certain domain of phenomena and its limitation to a particular set of causal factors, which predominate in this domain. With respect to this domain, economists can (at a certain level of approximation) ignore the myriad causal factors that influence all social phenomena (and that are the subject matter for other social sciences) and develop economics separately. In defending a view of economics as in this way inexact and separate and a view of economists as following the method a priori, Mill was able to reconcile his empiricism and his commitment to Ricardo's economics.

Although challenged later in the nineteenth century by dissident economists who believed that economic theory was too remote from the contingencies of policy and history, Mill's methodological views dominated the mainstream of economic theory for over a century. Mill's vision survived the transformation of economics from classical to neoclassical, and it is clearly discernible in the most important methodological treatises concerning neoclassical economics, such as John Neville Keynes' *The Scope and Method of Political Economy* (1891) or Lionel Robbins' *An Essay on the Nature and Significance of Economic Science* (1935). Hausman (1992) argues that current methodological practice closely resembles Mill's methodology.

Twentieth Century Philosophy of Science and Economic Method

Beginning in the 1930s, mainstream economists began to have a bad conscience about their traditional methodology, which some saw as insufficiently empiricist. Robbins is a transitional figure, because at the same time that he clung to Mill's methodology (1935: chap. 4) and to the identification of the domain of economics with the predominance of particular causal factors (the allocation of scarce means that have alternative uses – 1935: chap. 1), he also offered an apparently empiricist critique of interpersonal utility comparisons as untestable value judgments (1935: chap. 6). Terence Hutchison argued that the propositions of pure theory are so hedged with *ceteris paribus* conditions that they are not testable (1938). Paul Samuelson argued for a need to separate the 'operationally significant' economic wheat from the chaff, and in his theory of revealed preference he provided a model for how to do so (1947). Other economists cited survey data to argue that the theoretical propositions of economics were false. The confusing methodological situation stabilized in the 1950s with arguments by Fritz Machlup (1955) and especially Milton Friedman (1953) that economists need be concerned to fit only data concerning prices and quantities and that they need not be concerned about the 'realism of assumptions.'

Although confused, mistaken, and inconsistent with the practice of mainstream economists – including his own practice – Friedman's views have dominated the methodological conceptions of mainstream economists over the past two generations. His views are confused because they conflate many different kinds of 'assumptions' and many notions of 'realism.' Basic generalizations, propositions concerning initial conditions, and antecedents of conditional claims are all called 'assumptions.' Assumptions are called 'unrealistic' if they are false, incomplete, or not approximately true. Friedman's views are mistaken, because (as Mill already emphasized) market data are generated by too many causal factors to provide effective tests of economic theory. The eclecticism that Friedman's official methodological position counsels – 'don't worry about what theory says, just ask whether it fits market

data' – contradicts the firm and narrow commitment to a specific theory that characterizes mainstream economics, including Friedman's own work. Nevertheless, Friedman's views were warmly embraced. They freed mainstream economists to ignore criticisms of their theories and to abandon all empirical work apart from econometrics.

In the 1970s and 1980s, other streams of contemporary philosophy of science began to influence the methodological reflections of economists. Karl Popper's view that scientific theories must be falsifiable, which had been defended by Hutchison, was taken up and emphasized by Mark Blaug (1992). According to Popper, the hallmark of science is to formulate theories so that they can be exposed to empirical testing and to reject theories that fail tests. Hutchison and Blaug object that mainstream economic theories are not harshly tested and that mainstream economists are unwilling to surrender them when they fail the few tests they are subjected to. In his extensive publications, Lawrence Boland (1982) has also emphasized the relevance of Popper's views to economic methodology, although Boland's interpretation of Popper is rather different than Blaug's or Hutchison's.

Imre Lakatos' methodology of scientific research programs (which represented a wedding of some of Thomas Kuhn's insights to Popper's philosophy of science) was for a while widely discussed by economic methodologists (Latsis, 1976; de Marchi and Blaug, 1991). Although still emphasizing the importance of empirical criticism, Lakatos insisted that theories should not be abandoned until superior alternatives are found, and his emphasis on informal rules or heuristics governing theoretical practice struck a responsive chord.

A spate of prominent writers on methodology: Roger Backhouse (1997), Bruce Caldwell (1991), Hands (1992), and Weintraub (1985) have a more ambivalent relationship to Popper's and Lakatos' philosophy. Caldwell offers searching though charitable criticisms of Popperian views. Backhouse, Hands, and Weintraub were all at one time enthusiastic about Lakatos' views, but, to differing degrees, all have moved away from them now. Hands (2001) has become a proponent of the application to economics of new work on the sociology of science, while Weintraub's work (1991) on the stabilization of concepts in economics has been more influenced by literary theorists.

Alternatives to philosophy of science influenced by work in literary theory and sociology have recently developed a following among economists. In a series of stylistically brilliant works, Deirdre McCloskey has criticized the whole project of exploring a normative methodology for economics and has urged instead that economists attend to their rhetoric – that is, to their ways of persuading one another (1985). This work has been controversial because many of McCloskey's formulations apparently reduce questions about the correctness or incorrectness of economic claims to questions about what most economists accept. Such a view would imply that minority views are always mistaken. McCloskey denies such a radical reading of her position, but it is not clear how to avoid it without incorporating normative methodological commitments into the rhetoric of economics.

Philip Mirowski's work on methodology is heavily historical and less radical epistemologically than McCloskey's. He has explored the influence on economics of the formal analogy between utility theory and physics (1989). More recently, his work has shown increasing concern with sociological influences (Mirowski and Sent, 2002). For other work that tests the boundaries of conventional methodology, see Mäki et al. (1993), Davis et al. (2004), and Kincaid and Ross (2009).

Other recent developments in economics and its methodology have been the articulation of feminist insights into the subject matter and conduct of economics (Barker and Kuiper, 2003; Ferber and Nelson, 2003; Nelson, 1996) and the explosion of work in experimental and behavioral economics and of methodological reflection on that work (Camerer et al., 2005; Caplin and Schotter, 2008; Glimcher et al., 2009; Guala, 2005; Kagel and Roth, 2008; Loewenstein, 2007).

Over the last generation, economic methodology has become a large field. It has its own *Journal of Economic Methodology* an annual series, *Research in the History of Economic Thought and Methodology*, and discussions of economic methodology occupy a large part of the journal, *Economics and Philosophy*. Dozens of monographs on economic methodology have been published. Graduate programs in the field have been established (including a PhD program at Erasmus University in Rotterdam) and a Masters program at the London School of Economics, and there are regular sessions on economic methodology at meetings of economists and philosophers. The field is diverse, and each of its leading figures has a distinctive approach. Although one can roughly identify Popperian–Lakatosian and sociological–literary schools, there is no easy way to categorize contemporary methodology. Here is a sampling of the specific approaches.

Several methodologists have been particularly interested in the role of explicitly causal notions in economics. Nancy Cartwright (2007), who is also a distinguished philosopher of physics, has (unlike most philosophers writing on economics) paid a great deal of attention to econometrics. She has defended the importance of specifically causal considerations in science, and has argued that econometricians have made important contributions to a philosophical understanding of causation. Cartwright holds that economists should be understood as attempting to identify causal *capacities* and that the work of econometricians can be understood as contributing to this task.

Daniel Hausman (1992) defends a modernized variant of Mill's methodology that depicts economics as inexact and permits the plausibility of the basic principles of economics to count in the assessment of economic theories. But he is skeptical of the view that a small set of causal factors do indeed predominate in the domain of economics, and he argues for greater attention to the results of experiments, surveys, and field work (which has to some extent come to pass with the increasing importance of experimentation and studies invoking instrumental variables to simulate experiments (Deaton, 2010)). Hausman has increasingly emphasized the role of causal generalizations in mainstream microeconomic theory and the interrelation between issues in methodology and ethics (2011).

Kevin Hoover (2001a,b) has written on problems concerning macroeconomics and causality. Although he has addressed technical issues in econometrics, his main interest has been in causality. Like Cartwright, Hoover has placed

particular emphasis on what one can learn about causation by studying the work of economists, but he has also attempted to apply insights from philosophical accounts of causation to economics.

Tony Lawson (1997; see also Fullbrook, 2009) finds his inspiration in the 'transcendental realism' of Roy Bhaskar. Lawson sees himself not merely as enunciating a distinctive approach to methodology, but as laying the foundations for a new economics. Crucial to the approach and to his methodological views is a strongly realist ontology which takes the objects of scientific investigation to be causal mechanisms and tendencies that lie as it were 'beneath' the irregularity of phenomena.

Uskali Mäki's work is harder to categorize. Like Lawson, he is concerned with realism, but whereas Lawson attempts to redirect economics and its methodology on the basis of a specific realist ontology, Mäki elucidates versions of realism to which economists have been implicitly committed (2007). Like Cartwright, Hausman, and Hoover, Mäki emphasizes the importance of causal notions in economics. Like Hands and Mirowski, Mäki also applies insights from the sociology of science to the understanding of economics.

Alexander Rosenberg, who is also a distinguished philosopher of biology, began his career arguing that economics fits reasonably well within a standard philosophical model of the natural sciences. But by the early 1990s, he became convinced that the discipline has little empirical content and is best understood either as applied mathematics or as a normative social and political theory (1992).

Geoffrey Hodgson (2004) espouses an evolutionary approach to economics, influenced by institutionalism. John Davis (2011) argues that an appreciation of concepts of identity in economics clarifies economic methodology. Many writers on methodology are committed to the extreme subjectivism of the so-called Austrian School (Boettke, 2010).

Current heated controversy concerning macroeconomic policy has also generated considerable methodological reflection (Backhouse, 2010; Jespersen, 2009), including reflection by the warring parties. A good deal of the latter can be found on the web logs such as those by: Gary Becker (www.becker-posner-blog.com), John Cochrane (johnhcochrane.blogspot.com), Paul Krugman (krugman.blogs.nytimes.com), J. Bradford deLong (delong.typepad.com), Gregory Mankiw (gregmankiw.blogspot.com), John Taylor (johnbtaylorsblog.blogspot.com), and Simon Wren-Lewis (mainlymacro.blogspot.com).

Contemporary economic methodology moves in many directions. Although some of it is directed toward the conduct of economics, one regularly finds a sort of methodological schizophrenia whereby in theory economists cling to positivist or Popperian philosophical views that are radically at odds with their practice, which is roughly Millian. Other work in methodology is oriented toward the philosophy of science, and it appears that the study of economic methodology has made significant contributions to philosophical investigations of causation and explanation. It is controversial whether methodology can or should be a distinct and relatively self-contained field rather than addressing itself toward economists or toward philosophers. For a superb introduction, see Julian Reiss's *The Philosophy of Economics* (2012). Other especially useful sources include Davis et al. (1998), Davis et al. (2004), Kincaid and Ross (2009), and Mäki (2012).

Methodology, Rationality, Preference, and Self-Interest

The study of rationality, preference, and self-interest is a second area of overlap between economics and philosophy. Mainstream economic theory is built around a variant of 'folk psychology.' According to folk psychology, human actions are the consequence of beliefs, desires, and circumstances that determine the feasibility and consequences of actions. The same elements figure in economic theories of choice. Sometimes economists suppose that agents have complete knowledge and thereby avoid having to refer specifically to beliefs, but in other contexts beliefs are explicitly modeled – most typically as subjective probability judgments. In place of desires, which need not be comparative, economists postulate that economic agents possess stable, complete, and transitive comparative evaluations or preferences. Given additional technical conditions, preferences can be represented by a continuous 'utility function' such that $U_P(A) > U_P(B)$ if and only if an economic agent P prefers A to B. 'Utility' is simply a way of indicating how an alternative is ranked by an agent. It is not a substantive object of choice, and it makes no sense to regard an agent as seeking or preferring utility. Mainstream economic models relate choice to preference by maintaining that, subject to the constraints, agents maximize utility – which means merely that, among the alternatives agents believe to be feasible, agents choose whatever they most prefer.

The previous paragraph presents the standard theory of choice as an empirical theory purporting to describe, predict, and explain how agents choose in fact. But the same theory also functions as a theory of rationality. Preferences are rational if they are complete and transitive (and perhaps satisfy other axioms, too). Degrees of belief are rational if they satisfy the axioms of the calculus of probability. Choices are rational if they are determined by preferences. Given this model of rationality, the empirical claims of the standard theory of rational choice can be restated simply as the claim that economic agents are in fact rational.

According to this theory of rationality, it is irrational to choose one feasible option over another when one prefers the second, and according to this theory of choice people will in fact never choose one feasible option over another if they prefer the second (and know what alternatives can be chosen). Since, according to these theories, choice is and ought (rationally) to be determined by the agent's preferences, it is easy mistakenly to infer that these theories maintain that agents are and ought to be self-interested. But whether a choice is self-interested depends on the *content* of the preferences that drive it, not on whether the choice is determined by preferences. People who prefer to sacrifice their interests in order to benefit or harm others are not self-interested, and the fact that their choices result from these preferences does not make their choices self-interested. Unlike the standard theories of choice and rationality, the views that it is rational to pursue one's own interest and that people in fact do so are 'substantive'

theories of choice and rationality. Unlike the standard 'formal' theory, which merely specifies a certain *structure* of choice and preference, self-interest theories specify an objective that agents do or rationally ought to have.

Theories of rationality are normative theories. They *prescribe* what one ought to do – not, to be sure, as a matter of morality, but as a matter of rationality or prudence. (Irrationality is foolish rather than evil.) Incorporating as it does a normative theory, economics is unlike any of the natural sciences. The reason why economics incorporates a theory of rationality is that human actions, unlike the actions of oak trees or potassium, can be criticized or justified as well as explained. This fact has important methodological consequences and indeed (as just argued) establishes one important distinction between the social and the natural sciences.

The first and perhaps most important methodological consequence is that explanations of individual choices cite the *reasons* why the agent acted. Although a number of philosophers in the 1950s, who were influenced by Wittgenstein, argued that explanations that cite an agent's reasons could not be causal explanations, nowadays most philosophers have been persuaded by Donald Davidson's argument (1963) that successful explanations that cite an agent's reasons must also be causal explanations. Merely citing an agent's reasons is not enough if those reasons were not in fact responsible for the action. Davidson argued that the distinction between the reasons that are 'effective' and those that are merely rationalizations is that the first unlike the second are causes of the action.

So the fact that the explanations economists offer of individual choices cite reasons for those choices does not imply that economists are not giving causal explanations, and it diminishes the differences between the structures of the natural and social sciences. But the fact that the causal explanations economists offer also cite reasons remains. It explains why economists must hold that agents are to some extent rational. (If they were not, then they could not have reasons for their actions.) Furthermore, it implies that the actions of economic agents are subject to rational *appraisal*. Were the agent's reasons *good* reasons? Was the action *justified*? Once one begins appraising choices, one is just one step away from ethical questions. Readers should be aware that the standard theories of rationality and choice are controversial.

Welfare, Justice, Equality, and Freedom

Economists have an ambivalent attitude toward ethics. On the one hand, many have insisted that mainstream economics – including welfare economics (!) – is a 'positive' science, whose conclusions are independent of any moral commitments (Gul and Pesandorfer, 2008). On the other hand, economists freely give out normative policy advice. Some of this advice is purely technical, like the advice that a civil engineer might offer on where to locate a bridge, but much of it is not. Most mainstream economists are in fact committed to a specific view of ethics that emphasizes welfare, and they also adopt a distinctive theory of welfare. (When economists emphasize *efficiency* they are usually concerned with efficiency at promoting individual welfare.) These features of normative economics are not entailed by positive economics or the theory of rationality, but they are heavily influenced by them.

There are a variety of different ethical bases for assessing social arrangements. In addition to considering individual welfare, one can ask whether individual rights are protected, whether procedures and distribution are just, whether people are treated equally, and what freedoms and opportunities people enjoy. All of these considerations are important, but in economic policy pronouncements and normative theory (which indeed is called 'welfare economics'), typically only considerations of welfare enter.

The reason for this narrow normative focus is that welfare can be tied tightly to the standard models of rationality and choice. Suppose that individuals are rational and self-interested. As already pointed out, the standard theory of rationality does not imply self-interest, but self-interest is also commonly assumed in most economic models. It follows that individuals will prefer alternative A to B if and only if they believe that A serves their interests better than B. If individuals are good judges of their interests, which is not always the case, but which economists often assume to be the case, it follows that individuals will generally prefer A to B if and only if A in fact serves their interests better. So A is better for an individual than B if and only if the individual prefers A to B – or, in other words, welfare coincides with the satisfaction of preference. This view of welfare has the additional advantage that it prevents concerns about paternalism – to which many economists are opposed – from even arising, since by definition it could never be good for individuals to overrule their preferences.

Most normative economics is thus doubly narrow. Not only is it characterized by an almost exclusive preoccupation with welfare, but it is also committed to measuring welfare by the satisfaction of preferences. This double narrowness is unfortunate. The limitation to considerations of welfare means that in policy discussions economists treat nonwelfarist ethical criteria as additional factors to be left for someone else to worry about. And in practice this often means that other morally relevant factors are ignored altogether. The commitment to measuring welfare by preference satisfaction has the drawback that people do not always prefer what is good for them, because they are often misinformed, not fully rational, and not purely self-interested. There are a variety of good reasons to be hesitant about paternalism, but the view that individuals are always perfect judges of their own good is not one of them. There is some work, particularly by Amartya Sen (1992), that stretches these limits on normative economics, but such work is the exception to the welfarist rule (see also Hausman and McPherson, 2006).

Conclusions

Mainstream economists, whether engaged with positive theory, the theory of rationality, or with normative and policy investigations, are overwhelmingly committed to an exaggerated simplification of a plausible view of individual agents as possessing stable and consistent preference rankings, which, given their beliefs and the constraints, determine their choices.

Market outcomes are the unintended consequences of these choices. Rationality is defined by this structure of choice. Welfare can be inferred from these same preference rankings. Although there are many philosophical issues concerning economics that have no particular connection to this core commitment and that are now commanding increasing attention, most work in the philosophy of economics has attempted to comprehend and evaluate the basic model of choice and its applications in positive economics, normative economics, and the theory of rationality.

Abstract

Ecotourism is widely recognized and promoted as a sustainable form of nature-based tourism, often with cultural components. Such attention has commanded a great deal of academic work, use by development practitioners, and a United Nations designated 'year of ecotourism' in 2002. However, it is clear that ecotourism has not always been able to deliver on its promises. This is often a result of misinterpretation of what ecotourism means in different contexts and cultures, and its links to broader tourism and development objectives.

Ecotourism emerged as a concept in the early 1990s to rapidly capture the imagination of practitioners and academics alike. The Ecotourism Society (later to become *The International Ecotourism Society*, TIES), based in the United States, was formed in 1990, showcasing at the first International Conference on Ecotourism in the Caribbean in 1991, and the Journal of Ecotourism began publication in 2002. Ecotourism's appeal centered on the fact that it not only embraced the essential principles of sustainability (*see* Sustainability: A Dialog of Values), thus constituting a form of sustainable tourism, but also, in doing so, that it could make a significant contribution to sustainable development (SD). Sustainable tourism is typically intended to result in a symbiotic, win-win, scenario with environmental protection resulting both *from* and *in* improved local livelihoods; continued, and possibly even enhanced, profits for the tourism industry; sustained visitor attraction and satisfaction; and revenue as well as popular support for conservation (embracing the 'use it or lose it' philosophy: simultaneously making conservation pay and paying for conservation). The very incorporation of the prefix 'eco' in the term indicates the close relationship between ecotourism and the environment. Indeed, three out of the five core principles of ecotourism outlined by Page and Dowling (2002), that it is nature-based, ecologically sustainable, and environmentally educative, emphasize this closeness and are regarded as essential attributes of ecotourism. The remaining two fundamental requisites, that it should be locally beneficial and generate tourist satisfaction, are viewed as being desirable for all forms of tourism.

Recognition of the contribution that ecotourism could make toward SD in general and of the relevance of tourism to the poverty agenda in general during the 1990s led to international lending and bilateral development agencies such as the World Bank, USAID, DFID (the United Kingdom), and GTZ (Germany) focusing their attention on ecotourism as one of the few options open to rural communities to develop natural resource uses that are sustainable and, fundamentally, as a means of enhancing local livelihoods. The high ground claimed by ecotourism, in terms of its contribution to development, is that, in principle, it offers much enhanced prospects for local involvement compared with conventional tourism. Major international environmental nongovernmental organizations, such as the World Wildlife Fund, Conservation International, and The Nature Conservancy, often acting as the implementing agencies for the donor bodies, placed ecotourism projects high on their agenda, and this degree of universal attention was ultimately reflected in the UN declaration of 2002 as the International Year of Ecotourism (IYE). This designation flew in the face of the fact that, despite extravagant claims to the contrary concerning its global significance (see, for example, the various estimates cited by TIES, 2000), the World Tourism Organization estimated that ecotourism constituted only 2–4% of global tourism (WTO, 2002).

Defining 'Ecotourism'

It is no coincidence that much of the discussion about ecotourism parallels the weighty debate surrounding the definition of SD (*see* Sustainable Development). This is because the high ground claimed by ecotourism is that it constitutes a form of sustainable tourism, an equally contested concept (see Cater et al., 2014). The term was first given popular airing in the early 1980s by Ceballos-Lascuarian, who suggested that ecotourism "consists in traveling to relatively undisturbed or uncontaminated natural areas with the specific objective of studying, admiring, and enjoying the scenery and its wild plants and animals, as well as any existing cultural manifestations (both past and present) found in these areas" (Weaver, 1998, p. 15). The internationalization of the concept, however, resulted in such a proliferation of definitions that David Fennell was able to conduct a content analysis of 85 of them only just over a decade later (Fennell, 2001). Rather than expand on these multifarious definitions and their evolution, a task that has been amply tackled in the literature (see, for example, Page and Dowling, 2002; Fennell, 2003), it is illuminating to examine the principal features of ecotourism outlined in The Quebec Declaration on Ecotourism (UNEP/WTO, 2002). Emanating from the World Ecotourism Summit, the focal event of IYE, and with a caveat that the 1200 participants were "aware of the limitations of this consultative process to incorporate the input of the large variety of ecotourism

stakeholders, particularly nongovernmental organisations (NGOs) and local and indigenous communities," the declaration recognized:

> that ecotourism embraces the principles of sustainable tourism, concerning the economic, social and environmental impacts of tourism. It also embraces the following specific principles that distinguish it from the wider concept of sustainable tourism:
>
> - Contributes actively to the conservation of natural and cultural heritage,
> - Includes local and indigenous communities in its planning, development and operation, and contributing to their well-being,
> - Interprets the natural and cultural heritage of the destination to visitors,
> - Lends itself better to independent travellers, as well as to organised tours for small size groups.
>
> (UNEP/WTO, 2002).

Deconstructing these requirements throws light on the complexity of issues and interdependencies implied in both the theory and practice of ecotourism.

Ecotourism as a Subset of Sustainable Tourism

By declaring that ecotourism embraces the principles of sustainable tourism, the Quebec Declaration implicitly acknowledges that ecotourism is not the only manifestation of that ilk. Many writers have positioned ecotourism as a subset of the wider concept of sustainable tourism (Cater et al., 2014), situating it in relation to this and other tourism types, for example, alternative, nature, adventure, cultural tourism (Fennell, 2003), and even mass tourism (Weaver, 2001). So, while ecotourism should, by definition, be sustainable tourism, not all sustainable tourism is ecotourism. What, then, are the specific attributes of ecotourism?

Distinguishing Principles of Ecotourism

Active Engagement

The Quebec Declaration's first principle that refines ecotourism from the wider concept of sustainable tourism is that it should contribute *actively* to the conservation of cultural and natural heritage. Orams (2001) classifies ecotourism types along a continuum from 'better' operations that actively contribute to the improvement of the natural environment, through 'neutral' operations that passively seek to minimize their impacts on the natural environment to 'worse' operations that are more exploitative and irresponsible, thus detracting from the quality of the natural environment (*see* Carrying Capacity of the Environment). Hence, the requirement to contribute actively to natural conservation positions true ecotourism at the 'better' end of the spectrum, emphasizing that ecotourism requires not only a behavioral/lifestyle change in the participant but also involves actions that contribute to the well-being of the environment (Weaver, 1998). Weaver (2005) articulates this as *comprehensive* ecotourism which encourages deep learning, a holistic perspective, and an 'enhancement sustainability' approach. This is in contrast to *minimalist* ecotourism offerings which involve "shallow or superficial learning opportunities in conjunction with specific charismatic wildlife and sustainability objectives that are status quo oriented and focused on a particular site" (Weaver, 2008, p. 17). A similar case can be made for cultural heritage.

Inclusivity

The Declaration's second principle, that of the inclusion of local and indigenous communities in its planning, development, and operation while contributing to their well-being, echoes probably the most vaunted principle of ecotourism, that of community involvement. This not only has important implications for development, hence the interest of donor agencies in ecotourism in poverty alleviation strategies and 'pro-poor tourism' (Ashley et al., 2001), but also for conservation, cultural sustainability, distributive justice, and efficient use of human resources. Early approaches toward community involvement in ecotourism were largely tokenist, involving manipulative, passive, consultative, or for-material-reward participation, none of which bring enduring effects on people's lives (Pretty, 1995). The Quebec Declaration, however, stresses the need for much more active participation in decision-making right from the outset so that:

> to achieve equitable social, economic and environmental benefits from ecotourism and other forms of tourism in natural areas, and to minimise or avoid potential negative impacts, participative planning mechanisms are needed that allow local and indigenous communities, in a transparent way, to define and regulate the use of their areas at a local level, *including the right to opt out of tourism development*.
>
> UNEP/WTO, 2002

Hence the last decade has seen the development of many examples of community-based ecotourism (CBET), but the most successful of these are those that have moved slowly to allow communities to articulate their vision of inclusive development effectively (Reimer and Walter, 2013). Much has been made of the potential for ecotourism to empower marginalized elements of communities, particularly women (Scheyvens, 2000). However, in their recent study of CBET development in Cambodia, Reimer and Walter (2013) identified the significant extra workloads placed on female community members in the operation of homestays and guesthouses relative to males engaged in ecotourism.

Educative

The third specific principle of ecotourism outlined at Quebec emphasizes the need to interpret the natural and cultural heritage of a destination for visitors. Indeed, Page and Dowling (2002) suggest that the educative element of ecotourism is a key element distinguishing it from other forms of nature-based tourism, arguing that ecotourism education can influence tourist, community, and industrial behavior, and assist in the longer-term sustainability of tourist activity in natural areas. They point out that interpretation helps to advance the cause of conservation as tourists see the big

picture regarding the environment (*see* Environmental Education and Education for Sustainable Development). Perhaps one of the clearest aspects to the evolution of the ecotourism concept, as identified by Boyd (2012), is a growing ethical reflexivity regarding responsibility and awareness from stakeholders. This may often present challenges in operationalization, but it sits within the urgent need for the tourism industry to engage with the triumvirate of Corporate Social Responsibility, ethics, and sustainability (Fennell and Malloy, 2007).

Small Scale

The Declaration's final specific principle of ecotourism is that it lends itself better to independent travelers, as well as to organized tours for small-size groups. Despite the wording of this codicil, which would allow for larger groups, the obvious preference expressed is for small-scale visitation. The question of scale is one of the most contested characteristics of ecotourism. However, confining ecotourism to small-scale participation not only brings the danger that enacting its principles in such confined contexts is tantamount to preaching to the already converted but also that it is irrational to deny the designation of ecotourism to large-scale nature-based tourism if it adheres to all the requirements of sustainable tourism. As Williams and Shaw (1998, p. 56) state, "While sustainability is often popularly associated with 'smallness'… the link between scale and sustainability has not been empirically (or theoretically) tested." The debate about scale serves to illustrate the heterogeneity of ecotourism. It has become increasingly recognized that a spectrum of participation and involvement can be discerned from hardcore specialist groups, frequently undertaking scientific observation (Wood, 2010), to more casual natural resource-based activities, such as whale-watching, providing they are sustainably managed. Weaver (2001) identifies the latter as a 'soft' (and perhaps minimalist) ecotourism market which may largely consist of 'mass tourists engaged in such activities as part of a broader, multipurpose vacation that often places emphasis in the 3S realm' arguing that most ecotourism activity in the high-profile ecotourism destinations of Costa Rica and Kenya fits into this category. Care should be taken when examining small-scale 'hard' ecotourism operations in a broader sustainability context, for they may have higher global impacts, especially when it comes to climate change. For example, Becken and Simmons (2002) illustrate in the New Zealand context how energy use for ecotourism activities such as 'watching wildlife in a natural setting' are up to 60 times as energy intensive (often requiring the use of four-wheel drives or boats) as traditional tourism activities such as shopping or heritage attractions.

Ecotourism in Practice

There has been much disappointment registered concerning the failure of ecotourism to deliver its promises. For example, an early analysis of 23 Integrated Conservation and Development Projects, most with ecotourism components, found that few of the benefits went to local people or served to enhance protection of adjacent wildlands (Wells and Brandon, 1992).

As with all ideals faced with the harsh realities of the marketplace, it is hardly surprising that there is considerable divergence between theory and practice. This is not the fault of ecotourism per se but can be attributed to two major factors. The first is the failure to recognize the wider context in which ecotourism is set as a process; the second is that its 'sexiness' as a concept has meant that, either through a failure to understand or blatant opportunism, ecotourism has frequently been misinterpreted, misappropriated, and misdirected. Consideration of each of these in turn reveals why an increasing number of antagonists have voiced fundamental concerns about its wholesale adoption across the globe.

The Wider Socioeconomic and Political Context

The wider context in which ecotourism is set as a process and as a principle is vitally important, because that context has a vital role to play in prospects for sustainable outcomes. It is essential to recognize that place characteristics both shape and are shaped by economic, sociocultural, political, ecological, institutional, and technical forces that are exogenous and endogenous as well as dynamic. These forces may have enabling or constraining effects (Hall and Page, 1999) and are dictated by scale and circumstance (Lew and Hall, 1998). There are seemingly limitless combinations and permutations of these forces that either make for or militate against sustainable outcomes because of place and time specificity. However, there are certain general, recurrent themes which give rise for concern. One of the most significant is the failure to recognize the economic milieu in which ecotourism is cast as a process.

There is an inherent danger of regarding ecotourism as an isolated alternative, disassociating it from all other forms of economic activity. There are various scale levels to consider and sectoral conflicts may compromise the success, if not the very existence of ecotourism.

Also, it is essential to consider the global context within which ecotourism is cast as a process. Despite its emphasis on local involvement, it is not exempt from patterns of center–periphery dominance inherent in the international organization of the tourism industry. Ecotourists originate largely from the more developed countries and consequently their tour, travel, and accommodation needs are largely coordinated by firms based in those countries. Such patterns of dominance have led to accusations of ecotourism as 'eco-imperialism' or 'eco-colonialism' (Hall, 2000; Mowforth and Munt, 2001). As will be examined below, this is perhaps the most fundamental criticism of the concept. Further, the commodification of nature and culture in ecotourism products that are higher in status value for richer Western tourists has been critiqued by Wheeler (1994) as 'egotourism,' supporting the narrative cachet of guests more than a meaningful contribution to hosts or the environment.

Paying regard to the overall context means that, as with any other economic activity, we cannot escape from the fact that ecotourism is both shaped by and shapes the markedly inequitable structure, both internationally and intranationally, in which it is cast as a process. There is no substantiation with hard facts to guarantee the claim that ecotourism generally contributes to a more equitable distribution of tourism income and a reduction in poverty. Indeed, it has been argued that

ecotourism may even exacerbate, or even create, divisions due to structural inequalities.

The Misappropriation of Ecotourism

There is increasing concern, particularly from Indigenous Rights Groups and NGOs based in the South, that ecotourism misappropriates nature and culture, not only imposing an essentially Western-centric ethos on societies which have different values, but also simultaneously effectively commodifying the environment and traditional practices.

The accusation is that ecotourism, as constructed by the West, attempts 'to force people everywhere into the same cultural, economic, and political mold' which 'is bound to generate insecurity, resentment, conflict, and even ecological degradation' (Vivanco, 2002, p. 26). This question of ethnocentricity may even create schisms between seemingly consensual viewpoints. Hinch (2001) surmises that, at first sight, the ecocentric world view of 'true' ecotourists should be congruent with that of indigenous cultures who tend to see themselves as being one with the land. However, he highlights potential discord should the ecotourists witness the hunting or trapping of species that may be an essential component of traditional livelihoods.

It is also undeniable that traditional cultures frequently constitute an important component of the composite ecotourism attraction for the Western visitor. The view that outsiders may have of traditional lifestyles may also be viewed as patronizing. In the same way that antidevelopmentalists romanticize the lifestyles of indigenous peoples (Corbridge, 1995) so, too, may Western-constructed ecotourism assume an artificial, 'zooified' lifestyle on local populations, simultaneously assuming that the poor are happy as they are.

Another aspect of misappropriation is that ecotourism appropriates and commodifies both nature and culture. This is problematic for three major reasons. First, indigenous peoples voice their concern that outside interests have no right to expropriate local resources in this way. Second, as Hinch (2001, p. 347) points out "Indigenous people have a much deeper connection with the land than nonindigenous peoples. Because they do not see the land as a possession, they are very wary of treating it as a commodity, even in the purportedly benign context of ecotourism." The complex nature/culture relationship means that cultural erosion may result in the disintegration of social mechanisms governing resource use and allocation. Further, it is rarely indigenous populations who develop and own ecotourism development, as there are many cases of in migration of outsiders who facilitate and benefit from ecotourism development. Witness, for example, the description of marginalization of indigenous inhabitants in Lombok, Indonesia (Schellhorn, 2010), or the appropriation of Dai culture by Hani incomers for tourism purposes in Xishuangbanna, Yunnan, China (Walter, 2004). Absence of cultural identity may lead to an individualistic approach to property rights that eventually leads to resource commercialization. The inevitable commodification of nature and culture with Western-envisaged ecotourism, whereby a financial value is attached to natural and cultural resources, may have a serious knock-on effect. This is that, once a financial value has been attached in this way, should ecotourism present an unattractive investment prospect because of market disincentives, or even fail because of unfair competitive advantage, there is the clear danger that ecotourism entrepreneurs will look toward other more financially advantageous investment options with reduced consideration of environmental and cultural impacts, the expectations that are thus raised might push local populations into other, less sustainable, livelihood options. Furthermore, we are frequently talking of the commodification of natural and cultural resources by outside interests which reinforce Western hegemony.

Ecotourism as a Western-Centric Construct

It is against the backdrop of the global power–knowledge nexus (Blaikie, 2000) that we need to critically examine ecotourism as a Western construct (Cater, 2006). Because it may be seen to both reinforce and be reinforced by Western hegemony, as Duffy (2002, p. 156) suggests, "like other neoliberal policies, ecotourism creates a series of problems." We have considered the influence of supranational institutions above and international agencies above: ecotourism has been mainstreamed by these agencies with both a global reach and an intensifying influence.

It is undeniable that the power relations described currently give rise to a situation where Western ideology is dominant and all powerful. Cohen (2002) echoes this concern with regard to the concept of sustainability in tourism development in general, arguing that it is open to misuses, "not only in the obvious sense of misleading or fraudulent promotion, but in the more insidious sense of its use as an instrument of power in the struggle over rare and valuable environmental or cultural resources."

There is also the consideration that the translation of ecotourism into practice often translates into elitist operations. Whatever the calls for ecotourism operations to be basic and low-key in theory, there is a marked tendency for it to translate into expensive and exclusive in practice. Cohen (2002, pp. 272–273) examines how, as pristine, 'undiscovered' sites become increasingly more difficult to find, their rarity means that they constitute a 'new economic resource' and unspoiled sites harboring particularly valuable natural or cultural attractions tend to become the most expensive ones.

The preexisting political ecology of the destination prejudices sustainable outcomes when ecotourism is translated into practice (Wang et al., forthcoming). Walley (2004, p. 264) in her analysis of the 'social drama' of Mafia Island Marine Park draws attention to the fact that all that we witness may be a repackaging of the status quo such that "the merging of conservation and development agendas, the isolation of ecotourism as a development strategy, and the role of participation and transnational bureaucracies, are not ruptures, but rather build upon and work through existing and historical institutional structures and power relationships."

So, we are faced with a situation where the dominant, Western-centric, environmental imagination has given rise to what Vivanco (2002) calls ecotourism's 'universalistic and self-serving vision.' Another danger of this ethnocentric bias is that it ignores the fact that there are 'multiple natures' constructed variously by different societies. As Macnaghten and Urry (1998, p.95) declare "there is no single 'nature,' only natures. And these natures are not inherent in the physical world but discursively constructed

through economic, political and cultural processes." With the burgeoning domestic and regional tourism in developing and transitional economies, it is increasingly evident that nature tourism is variously constructed by different societies and therefore there are multiple 'nature tourisms.' Buckley et al. (2008), for example, illustrate how the concept of ecotourism is understood in China as Shengtai Luyou, with a particular focus on human and natural 'health' outcomes.

Prospects for Sustainable Ecotourism

It is not surprising that, in common with, and very much allied to, SD, ecotourism is a much contested concept in both theory and practice (Boyd, 2012). The contingencies of time and place mean that it is at the local level that such contestations should occur but serious reservations regarding its provenance and universal relevance have perhaps led to a weakening of its former eminence as alternative, broader terms such as responsible tourism have been introduced in the industry. It is misguided to take issue with the broader philosophy behind ecotourism but problems arise when there is a failure to recognize that it is but a process set in an interdependent world characterized by difference and diversity. It is when the concept is translated into a universal template, largely Western conceived, that it becomes clear that it is not a case of 'one-size-fits-all.' Contexts vary enormously across space and time. It is undeniable, however, that the whole debate surrounding sustainable tourism in general (Cater et al., 2014), and ecotourism in particular, has raised awareness of the pitfalls of ethnocentricity in tourism planning. Wearing and McDonald (2002, pp. 201–202) cite Prakash's call for "a radical re-thinking of forms of knowledge and social identities authored and authorized by colonialism and Western domination" and they argue that, if ecotourism "is to succeed in its goal of cultural and environmental integrity, it requires the development of theory that contains that same integrity." The social appropriation of nature must be viewed in, and from, particular social, economic, and political contexts. Failure to do so will only result in continued disappointment, frustration, and resentment over the manifest shortfall between what ecotourism promises and what it delivers.

Ecumene

Abstract

An ecumene indicates a set of societies that are in persistent and effective interaction. While contacts and diffusion suggest regional continuities and homogeneities embodied in the anthropological notion of culture areas, in fact many historically important regions have been heterogenous, containing societies of uncertain borders and shaped by diasporas of cultural groups, multiculturalism, cultural creolizations resulting from different forms of contact, and dynamic center-periphery relations in which dominant areas were the fountainheads of cultural innovations; such regions may be called ecumenes. Over the past half-millenium, spurred by the worldwide expansion of the West, much of the world has begun to constitute a single global ecumene or world-system. While some historians have treated this development as quite unprecedented in world history, other historians have pointed out that similar systems, on a smaller though continental scale, have shaped world history for several 1000 years.

Ecumene (sometimes oecumene) is a rendition of the Greek word *oikoumene,* which the ancient Greeks applied to the inhabited (i.e., known to them) world. It conveys a sense of communion (as, notably, in religious ecumenism), a community of independent but interacting members, or a set of separate but interrelated societies and cultures. The notion is useful to anthropologists, geographers, historical sociologists, and world historians when they wish to indicate a large region that represents a sphere of persistent and effective interaction among a group of societies that have been influencing one another and have been shaped to some significant degree by a shared history. The concept of ecumene may thus serve to reflect the subdivision of the world into several separate spheres of culture-historical experience. More recently, with the growing interest in 'globalization,' the notion of a 'global ecumene' has emerged; the notion reflects the idea that the entire world is now becoming a single interaction sphere, and that processes (such as integration and constant cultural exchange) that used to characterize the more restricted ecumenes of the past now operate on a worldwide scale. This article will focus on the use of the term in anthropology, and to some extent in world history and historical sociology. The term has been most used by scholars interested in large-scale cultural dynamics over both time and space and who therefore tend to share in a common scholarly discourse.

Early Perspectives

Nineteenth century evolutionary anthropology (primarily Anglo-American) assumed that local societies were expressions of general cultural evolution; in effect, the ethnographic world was not mapped geographically but was viewed in terms of postulated temporal stages. By contrast, German ethnology (which was more firmly grounded in first-hand observation) emphasized the geographical distribution of cultural traits; it regarded cultural contacts and diffusion as the primary mechanisms of cultural dynamics. This fitted well with the commonplace experience that neighboring societies usually tend to be culturally similar, forming what German ethnology called 'cultural provinces' – a concept that stressed cultural continuities within regions.

Early twentieth-century American anthropology, whose worldview was derived from German anthropology by way of its founder Franz Boas, adopted this spatial perspective and saw the ethnographic world as being subdivided into 'culture areas' shaped by regional diffusion. This, however, was mainly true of the 'primitive' ethnographic world, which has usually been peripheral to the world centers of historically significant cultural developments. Even in the 'primitive' world, the diffusionist view raised some problems. The fact that North America, for example, had several culture areas rather than one, demanded some explanation of the cultural discontinuities between the culture areas (a problem that Ruth Benedict proposed to solve by postulating distinctive regional patterns of culture). When one turned to regions of historically complex societies (such as Europe, the Mediterranean world, the Middle East, and South or East Asia) one found long-standing interactions in the midst of marked cultural heterogeneity.

The mounting dissatisfaction with the simplistic view of a world organized into a series of disparate culturally homogenous areas led Alfred Kroeber (1945) to draw attention to the existence on the world map of a central and culturally diverse area of 'civilization' ('a great web of cultural growth' stretching from Gibraltar to China). Within it, there were centers of consistent creativity, generating ideas and techniques that diffused through this area and sometimes to the peripheral areas beyond. Kroeber adopted the term oikoumene for it and his discussion may be seen as an early and prescient invitation to deal with the wider non-'primitive' world from an anthropological perspective. In this view, a culture area became a particular kind of ecumene – local and relatively, but not entirely, homogenous. As Kroeber (1936) had previously shown, such an area exhibited center-periphery relations through which diffusion throughout it took place.

However, Kroeber's (1945) invitation to expand the anthropological vision to worldwide cultural dynamics had scarcely any takers (for an unusual exception, see Hewes, 1970). In the 1930s, anthropology began to abandon its regional ethnological perspectives in favor of a concentration

on cultural dynamics. This turn took two directions. It either studied them within single societies or, when it dealt with contact, it studied it as it occurred between two neighboring societies. In the latter case, anthropology did develop a rich collection of ideas about cultural transmission, but the notion of the ecumene had no place in such a locally focused endeavor and it lay dormant in anthropology for some 30 years. In the meantime, the issues it raised came to the fore among world historians and historical sociologists (see Grew, 1995).

World History

A 'universal history' had been a major project of the eighteenth century Enlightenment, and the idea was revived in the earlier twentieth century in the comparative analysis of civilizations by such historians as Spengler (1926–1928) and Toynbee (1934–1961). Though these comparative studies did not fashion a unified historical narrative on a world scale, they did bring to attention the existence of 'high' periods in the histories of non-Western societies. This undermined the Eurocentrism of world history of the time, in which the first ecumene of any importance seemed to have arisen only with the fifteenth century expansion of the West. Now, attention was being drawn to the dominance of preceding regional ecumenes, such as the Islamic world or China-centered eastern Asia, with the West being frequently peripheral to them. Some historians, notably McNeill, 1963), began to frame world history in terms of a succession of dominant ecumenes, thereby wrenching it out of the complete grip of Western history.

The disappearance of the Western colonial empires after the Second World War reinforced the trend, for it raised questions about the very primacy of the West in world history, the reasons for it, its transience, and the lessons all this held for the immediate future. Here, post-colonial political and sociological concerns merged with historical ones, calling into being a historically oriented political science and political sociology. To be sure, the focus at first remained Eurocentric, as shown in one of the first formulations of these new perspectives – that by Wallerstein's (1974) 'world-system' analysis. Wallerstein took modern Western expansion to be a historically unique occurrence arising from specifically Western historical factors, such as the rise of capitalism. Nevertheless, the formulation was a first step toward an exceptionally fruitful debate and a series of analyses and reanalyses (e.g., Abu-Lughod, 1989; Frank and Gills, 1992; Smith, 1991).

The debate brought to historical consciousness a variety of preceding smaller 'world-systems,' ecu- menes that coexisted with one another in different patterns of integration, and that went back into prehistory. This new world history transcends the traditional national units and focuses on such interregional processes as long-distance trade, economic interdependence, interregional enterprise, large-scale imperial polities, and continent-wide cultural relations between centers and peripheries. It recognizes large areas of economic, political, and cultural interaction, their dynamics, and their periodic demise and reorganization into new ecumenes (Mazlich and Buultjens, 1993). As is natural with any new paradigm, it has led to detailed examinations of local dynamics of economic, political, and cultural exchanges. This development represents, in some sense, a retreat from worldwide perspectives and it often provides correctives to the sweeping assertions of the grand picture. But many of these local studies take the world setting as a necessary context for their analyses and thus address the broader issues.

Modern Anthropology

Similar currents began to sweep anthropology in the later 1960s. The paradigm that had dominated anthropology since the 1930s and that dealt with the systemics of single cultures was lapsing. The demise of colonial rule made an ahistorical approach to ethnography increasingly unrealistic, and this called attention to the larger forces swirling around the anthropologist's supposedly isolated societies. With the introduction of historicity into modern ethnography, it has become obvious that historicity is also necessary in dealing with the ethnographic past.

This new vision of former 'primitives' as being bounced about by the surrounding world was also reinforced by the popular journalistic discussions of 'globalization,' including large-scale international migrations, ethnic diasporas, world labor markets, economic integration, transnational economic and cultural flows, multiculturalism, cultural 'creolization,' the unifying role of the cyber net, and the divisive role of networks. These processes are sometimes seen as dismantling the separate old regional ecumenes that used to divide the world. What looms instead is a single community of interacting societies whose very borders appear increasingly to come into question – in brief, a single 'global ecumene' whose nature is being explored by anthropologists with the use of anthropological concepts (e.g., Foster, 1991; Hannerz, 1992). Thus, Kroeber's ancient oikemene has been transposed out of culture history and into the contemporary era.

In sum, the concept of the ecumene allows anthropologists to deal with interactions among disparate societies. Previously, the only concept that aggregated groups of societies was that of the culture area. But culture areas projected a homogenizing view of cultural interaction and it tied cultural diffusion to territorial continuities. The ecumene, by contrast, allows anthropologists a more realistic view of cultural dynamics – one in which very different societies interact and influence one another selectively and without ceasing to be different. As the mechanisms of such influence become better understood, it becomes clear that they can operate over discontinuous territory and thus encompass, in the modern age, the entire globe. At the same time, it should be noted that much of this new concern in anthropology has more to do with subject matter than theory, for it revives such old-standing anthropological interests as innovation, diffusion, culture contact, and selective acculturation.

Abstract

It is only recently that Edgeworth has become fully recognized as one of the greatest economists of his time, as well as one of its greatest statisticians. He was the author of over 300 publications in economics and statistics, so any brief biographical essay must perforce concentrate on just a few topics, those selected here being his life, his masterpiece *Mathematical Psychics*, and some of his pioneering statistical work. It was only after Edgeworth's classics degree at Oxford that, living privately in London, he started to study law, mathematics, physics, and the social sciences. His work in statistics began only after the uncomprehending reception of *Mathematical Psychics* in 1882, but it was essentially that work which in 1891 earned him the Drummond professorship at Oxford, a post he retained until 1922. He died at Oxford in 1926.

It is only recently that Edgeworth has become fully recognized as one of the greatest economists of his time, as well as one of its greatest statisticians–a unique combination. In both disciplines his best work was so subtle and profound that it took many years for its meaning to be understood. Edgeworth is thus a striking example of one whose reputation as an original thinker has grown ever since his death, slowly at first and then quite rapidly. After a century, Edgeworth's thought is only beginning to find an echo. *The future will no doubt acknowledge the profundity of his vision more and more* (Allais, 1978, p. 191, referring to *Mathematical Psychics* (1881); original emphasis, as in all quotations here).

Life

Francis Ysidro Edgeworth was born on February 8, 1845 at the family home Edgeworthstown in County Longford, Ireland, the youngest of five sons. His father Francis Beaufort Edgeworth (1809–1846) was one of 22 children of Richard Lovell Edgeworth (1744–1817), an inventor and educationist whose favorite child was the celebrated novelist Maria Edgeworth (1767–1849). Father and daughter were much interested in political economy and numbered among their acquaintance Bentham Malthus, and Dugald Stewart; after her father's death Maria also developed a warm friendship with David Ricardo.

Edgeworth's father, Francis Beaufort Edgeworth, was a favorite of both his elderly father and his half-sister Maria. His mother, 2 years younger than her step-daughter Maria, was Frances Anne Beaufort (1769–1865), of Huguenot stock and elder sister of the admiral who devised the famous Beaufort marine wind scale. Naturally averse to mathematics, Francis left Trinity College, Cambridge without a degree. After a brief courtship at age 22 he married Rosa Florentina Eroles (1815–1864), who was 16, poor, with 'beautiful eyes,' and daughter of an exiled Spanish general. After some years in Italy Francis struggled unsuccessfully as owner of a private school in Eltham near London, and in 1840 returned home to Edge-worthstown to run the estate. He died aged 37 after a long illness, in the worst year of the Irish famine.

Despite his disappointing career Edgeworth's father was not without talent. His writings on poetry and philosophy sufficiently impressed John Stuart Mill to lead him to enquire, in 1840, whether Francis might be available to tutor 'the eldest son ... of a person of very high rank,' adding mysteriously that 'there is, probably, no situation of the kind in England in respect to which more important consequences may depend on its being well filled' (Mineka, 1963, p. 439). Moreover, Francis's friendship was highly valued by the poets Alfred Tennyson and Edward FitzGerald and by the great mathematical physicist Sir William Rowan Hamilton.

Edgeworth himself was actually baptized Ysidro Francis Edgeworth, a form he sometimes used even as an adult. 'Marshall, remembering his mixed parentage, used to say: "Francis is a charming fellow, but you must be careful with Ysidro."' (Keynes, 1926, p. 152). He was educated by tutors at home, committing to permanent memory whole books of Homer, Virgil, Milton, and Pope. A notable linguist, he was well-read not only in classical Greek and Latin but also in French, German, Italian, and Spanish literature. In 1862 he entered Trinity College, Dublin to read classics and in 1867 transferred to Oxford, where in 1869 he gained a First in the honors examination in classics and philosophy.

He spent the next 22 years in London, living on the heights of Hampstead in two bare rooms that he continued as a *pied-à-terre* after he moved to Oxford in 1891. Supplementing his slim private means by occasional earnings as a part-time teacher in further education, he studied law systematically (specializing in commercial law) until he was called to the Bar at the Inner Temple in 1877; he never practiced. He also read widely in mathematics and physics, his interests perhaps influenced by those of his father's friend Hamilton. Certainly, by 1877 he had gained 'a confident and creative mastery of the calculus of variations' (Stigler, 1986, p. 306).

In 1871 he became an 'original' (and lifelong) member of the new Savile Club in central London, whose friendly and distinguished atmosphere apparently suited him well, so much so that during the years 1878–1882 he was quite active in the club's affairs as either a Committee member or an Honorary Secretary or both. Indeed, it was precisely then and not (as is sometimes alleged) as a reclusive Oxford don that he wrote and published *Mathematical Psychics* (1881). Two years later he began the many articles on probability and statistics whose quality carried him upwards through a series of appointments at King's College, London, until in 1891 he was appointed Drummond Professor of Political Economy at Oxford, tenable

at All Souls. He retired from this post in 1922 but the College remained his principal home until he died (from pneumonia) in Oxford on February 13, 1926. As the last surviving male Edgeworth in Europe he inherited the family estate from his brother Antonio in 1911 but did not live there.

Although Edgeworth never married it was not for want of trying. He was smitten by the handsome and imperious Beatrice Potter who found him 'gentle-natured ... excessively polite and diffident ... pathetic ... pedantic' – and boring, even though she glimpsed 'a hidden fire burning within.' Insufficiently discouraged, in June 1889 he published a glowing review of her early work and pursued her to a Co-operative Congress in Ipswich where, in spite of his 'agonized expressions of romantic regard,' she remained adamantly unimpressed (MacKenzie and MacKenzie, 1982, pp. 283–284, 286–287). Three years later she married Sidney Webb.

The words diffident, excessively polite, and pedantic recur often in friends' descriptions of Edgeworth's character, which perhaps accounts for Heilbroner's remark that: 'Neurotically shy, he tended to flee from the pleasures of human company' (1999, p. 173). However, just as frequently those same friends also described Edgeworth as affectionate, humorous, and kind; 'in my house ... few visitors were so beloved as he' (Bonar, 1926, p. 652). Known for his hospitality to foreign visitors, he had 'the widest personal acquaintance in the world with economists of all nations' (Keynes, 1926, p. 151). The young Joseph Schumpeter, visiting Edgeworth at All Souls, was memorably welcomed to breakfast by his host with 'rock pheasant' (presumably, cold roast grouse) and champagne (Samuelson, 1951, p. 53n).

Edgeworth was twice President of Section F of the British Association for the Advancement of Science (1889, 1922), President of the Royal Statistical Society in 1912, one of the original Fellows of the British Academy (1903), and an honorary Doctor of Civil Law from the University of Durham (1889). The most important of his few honors was his sole editorship of the *Economic Journal* (*E. J.*), which lasted from 1890 until J. M. Keynes succeeded him in 1911, whereupon he became Chairman of the Editorial Board. Keynes, busy at Versailles in 1919, co-opted Edgeworth to serve as Joint Editor and he continued active in this capacity 'up to the last day of his life' (Keynes, 1926, p. 140).

No complete bibliography of Edgeworth's prolific writings in economics and statistics has yet been published but an incomplete count yields four very short books, about 300 articles and shorter papers, and more than 200 book reviews. Perhaps reflecting his position as editor of the *E. J.*, after 1890 his major papers in economics tended to be surveys, learned and complex and delighting in brilliant paradoxes, rather than articles on original themes. Many of these, especially the surveys of the theories of distribution, index numbers, international trade, monopoly, railway rates, returns to scale, and taxation, he gathered together and reprinted in Edgeworth (1925). All his many papers in probability and statistics (except (1887) and a few others) were reprinted in 1996.

Mathematical Psychics

Although subtitled 'An Essay on the Application of Mathematics to the Moral Sciences,' *Mathematical Psychics* actually contains *three* analytically distinct essays, all rather jumbled together. The first is on methodology and comprises pp. 1–16 (undated page references here are all to (1881)); Appendix I – 'On Unnumerical Mathematics'; and Appendix II. It develops two separate themes, the first being a visionary stress on the importance of maximum problems for economics, at both the individual and social level. It goes on to argue that in many respects problems in economics are analogous to those of classical mechanics, so that '*Mécanique Sociale* may one day take her place along with *Mécanique Céleste*, throned each upon the double-sided height of one maximum principle' (p. 12). The second theme is less grandiose and develops in detail the importance of 'unnumerical mathematics' for positive economics. The emphasis here on second-order conditions for a maximum sounds very modern: 'the condition that a required curve shall be, or shall not be, convex ... this very relation of concavity, not a whit more indefinite in psychics than in physics... quarried from such data as the law of decreasing utility, of increasing fatigue, of diminished returns to capital and labour' (p. 92).

Edgeworth wrote most of his second essay, on the *Utilitarian Calculus*, when he was primarily a mathematically inclined philosopher. It consists of pp. 56–82 (which essentially reprints (1879)); Appendices III and IV; pp. 116–118 and 122–125 of Appendix VI; and pp. 126–134 of Appendix VII. Earlier, pp. 35–79 of his monograph *New and Old Methods of Ethics* (1877) had applied the calculus of variations and the psychophysics or Fechner and others to Sidgwick's utilitarianism. The resulting 'exact utilitarianism' sought 'the greatest quantity of happiness of sentients, exclusive of number and distribution,' where 'sentients' explicitly refer not just to mankind but to the whole animal creation (1877, p. 35). After a pioneering and detailed variational analysis, employing Lagrange multipliers for both finitely and infinitely many constraints as well as the idea of a continuum of rational agents, he concluded that for modern humankind '(T)here is no indication that ... a law of distribution other than equality is to be wished' (1877, p. 78).

The substance of some comments by Alfred Barratt on this monograph were incorporated in Edgeworth's article in *Mind* (1879), which enhanced his earlier analysis by considering the possible negative utility from work as well as positive utility from consumption; but also diminished it disastrously, by treating different individual capacities for enjoyment not, as before, as essentially random variations but instead as systematic differences in the sentient's position in the 'order of evolution.' This drastically modified his previous conclusions concerning the optimality of equal distribution, since now *'the more capable of pleasure shall have more means'* (1879, p. 398; 1881, p. 64), and led him to some startling arguments in favor of inequality.

When he wrote those indefensible passages Edge-worth was not yet an economist. But two years later, as virtually an apprentice in economics to his friend, neighbor, and mentor William Stanley Jevons, he wrote his masterpiece, the *Economical Calculus*. This third essay, entirely on positive economics, consists of pp. 16–56; Appendix V; pp. 118–122 of Appendix VI; and pp. 134–148 of Appendix VII. Its fundamental theorem asserts that: 'Contract without competition is indeterminate ... Contract with *perfect* competition is perfectly determinate ... Contract with more or less perfect competition is less or more indeterminate (p. 20). The wholly normative

analysis of the earlier *Utilitarian Calculus* depended critically on two doubtful assumptions, the cardinal measurability of individual utilities, and their interpersonal comparability, but this theorem needs neither of them. Indeed, it is richly ironical that Edgeworth, the most uninhibited of utilitarians, should have produced in this third essay the most far-reaching (though implicit) ordinalist analysis of any neoclassical economist.

Few works in economics have been so misunderstood as the *Economical Calculus*. Over the years commentators have discovered there not what it actually contains but only what their own preoccupations have predisposed them to find. For example, those with the *déformation professionnelle* sometimes induced by Walrasian general equilibrium theory have tended to confuse the aims of Edge-worthian recontract with those of Walrasian *tâtonnement*, while those who believe neoclassical economics to be overly tender towards capitalism have found in *Mathematical Psychics* 'a kind of Panglossian Best of All Possible Worlds' (Heilbroner, 1999, p. 173). This is travesty. Edgeworth believed that *imperfect* competition, with its few competitors, occurs frequently in economic life. Hence, by the theorem, indeterminate contract should occur frequently too, with its 'characteristic evil' (p. 29) of '*deadlock*, undecidable opposition of interests, unceasing strife and tumult' (the last phrase a translation of Edgeworth's Greek quotation from Demosthenes). This impasse would then lead to' a general demand for a *principle of arbitration*' (p. 51), a demand which Edgeworth proposes to meet by proffering the following utilitarian rule: the arbitrator should choose that contract which maximizes the total utility of all the parties concerned. 'Thus the *economical* leads up to the *utilitarian calculus*' (p. 56). In the theorem, *articles of contract* are whatever is subject to bargain, such as commodities or property rights, and parties may *recontract* away from any existing contract. *The field of competition* consists of *all* those parties (e.g., sellers and buyers) willing and able to enter into contracts for the articles in question. In these general conditions, which include 'the political struggle for power' (p. 16) as well as commercial exchange, there may well be neither prices nor markets for the articles. Hence, the theory of supply and demand in perfect markets, as already worked out by Jevons, Marshall, and Walras, does not apply to the general case of Edgeworthian contract and it becomes necessary to devise radically new concepts of equilibrium, appropriate to this general setting.

Edgeworth's first such concept is a *settlement*, 'a contract which cannot be varied with the consent of all the parties to it,' and the second *final settlement*, 'a settlement that cannot be varied by recontract within the field of competition' (p. 19). A settlement can, therefore, withstand any variation from it proposed by any party to the original contract, while a final settlement can withstand any variation proposed by any interested agent, whether an original contractor or not. A settlement is, thus, precisely an allocation that yields *maximum d'ophélimité*, a concept first defined 16 years later by Pareto and now known universally as *Pareto optimality*, its Edgeworthian origins long forgotten. Note that while settlement is a concept of positive economics, Pareto optimality belongs to welfare economics.

Edgeworth explicitly provides for coalitions, whose members may recontract between themselves in order to improve their positions under prevailing contracts. As pointed out first by Shubik (1959), from this perspective the set of final settlements is precisely the core of the relevant cooperative game. (While working with John von Neumann in late 1940, Morgenstern 'showed him the *contract curve*' (Rellstab, 1992, p. 83), but their epoch-making book of 1944 has no reference to Edgeworth.)

When there are only two agents they are the only possible contracting parties, so all settlements are also final settlements. Now for Edgeworth, competition necessarily involves at least three agents (see 1894, p. 378), so two agents represent ' (α) Contract without competition' (p. 19). For this case Edgeworth invented and deployed general utility functions and indifference curves to show that the final settlements form a continuous contract curve containing infinitely many points. Contract is, thus, completely indeterminate. (His analysis here remains central to standard micro-economic theory, which uses the 'exchange box' invented in 1906 by Pareto to amend Edgeworth's original exposition; by a delicious irony, economists usually attribute Pareto's device to Edgeworth!)

At the opposite pole to bilateral exchange lies perfect competition, where indefinitely many traders exchange infinitely divisible articles of contract among themselves. Here Edgeworth shows each resulting market equilibrium allocation to be a settlement (the first proof of the *First Fundamental Theorem of Welfare Economics*), as well as a final settlement. He conjectures the true result (proved rigorously 91 years later by Debreu and Scarf) that, in the perfectly competitive replica economy on which his analysis is based, every final settlement is a market equilibrium allocation of some initial endowment. Since the latter allocations are usually unique or at least finite in number, this shows that perfect competition is perfectly determinate.

Edgeworth next displays extraordinary technical virtuosity in dealing with the intermediate case of imperfect competition, where he proves that for a replica economy with $2n$ agents (where $1 < n < \infty$), the set of final settlements always shrinks in size as n increases, so that contract becomes less and less indeterminate as the degree of competition increases. The key property needed for this striking result is the strict convexity of individual indifference curves, which Edgeworth actually proves by using assumptions that imply cardinal measurability of utility, but which he could just as well have assumed directly, without need of cardinality.

This completes the proof of the theorem (for details, see Newman, 1994). As a coda, Edgeworth joyfully and correctly proves that his arbitration rule always produces a settlement. But this has two grave difficulties. First, the rule itself depends on cardinal measurability of utility. Second, an acceptable rule should produce not just a settlement but a final settlement. Otherwise, for some agents the utilitarian allocation might require their allocated utility levels to be below their initial levels, and so its implementation would require compulsory redistribution.

Works in Statistics

Soon after *Mathematical Psychics* appeared, and possibly influenced by Galton, Edgeworth became attracted intellectually by the ' law of error,' i.e., the normal distribution and the central limit theorem. For the next 10 years he devoted his formidable powers and energy to probability, mathematical statistics, and applied statistics, publishing over 30 papers and one brief

monograph (1887). Although subsequently he split his creative efforts more evenly between statistics and economics, in those later years he published a further 75 papers in statistics. R. A. Fisher rated Edgeworth of 'equal eminence' with Karl Pearson in statistics, while a distinguished historian of the subject has judged him to be the leading theorist of mathematical statistics of the latter half of the nineteenth century' (Stigler, 1987, p. 98).

Edgeworth set himself the task of adapting classical probability theory, developed originally by Pierre Simon Laplace and others for the physical sciences, to the problems of statistical inference in the social sciences. For example, regarding the returns of the Bank of England, to estimate the probability that the differences in the averages for different weeks and months are not accidental ... under what circumstances does a difference in figures correspond to a difference in fact' (quoted in Stigler, 1986, p. 308). In 1883 an early result of these efforts was possibly the first derivation of Student's t distribution (reprinted as McCann, 1996, II, No. 1), followed in 1885 by a pioneering version of the analysis variance for a two-way classification (McCann, 1996, III, no. 2).

His methodological views on statistical inference in the social sciences were given in his centrally important paper *Methods of Statistics* of 1885 (McCann, 1996, II, no. 3–this reprint has quite illegible diagrams). Generally, Edgeworth took an undoctrinaire Bayesian approach but was quite willing also to use frequentist methods rather than inverse probability, as when in 1905 he used significance tests to compare means (McCann, 1996, I, no. 26). In (1887) and elsewhere he stressed the importance of maximizing (expected) utility rather than probability in devising appropriate statistical procedures: 'what have we to do with probability or frequency, except as a guide to our actions?' (1887, p. 53). But that monograph has no hint of an axiom system that would unify probability and utility, such as those developed much later by Ramsey, de Finetti, and Savage.

He bequeathed his name to statistical posterity with his development in 1905 of a new series expansion – subsequently the *Edgeworth series* – as a means of adding correction terms to the central limit theorem in order to deal with skew distributions (McCann, 1996, I, no. 26). Less eponymous but more widely known is his term coefficients of correlation and his demonstration in 1892 of their role in expressing the parameters of the multivariate normal distribution (McCann, 1996, III, no. 16 and II, no. 21). A less appreciated novelty, anticipating R. A. Fisher, was his proof in 1908–9 of the asymptotic efficiency of maximum likelihood estimators (McCann, 1996, I, no. 12).

Finally, as so often with Edgeworth, a pioneering contribution in 1888 to inventory theory (McCann, 1996, III, no. 4) was ignored by economists and statisticians alike until very recently, even though it 'filled a gaping hole in orthodox classical monetary theory' (Laidler, 1991, p. 184). This delightfully written essay on banking demonstrated rigorously and quantitatively what had been known to bankers intuitively and qualitatively for centuries, that a bank's prudential reserve level rises proportionately, not with its liabilities, but with their square root.

Abstract

Gender and Education is a relatively recent area of inquiries in the history and sociology of education and it is a contested field of research, action, and policy making. In recent years the field has developed and expanded considerably and it is in continuous dialogue with the wider field of gender studies and feminist theories. Historically the field has addressed questions of equalities of opportunities, recognition, and representation. Contemporary debates in the field include new formations in the social construction of gendered subjectivities, sexualized identities, and the crisis of masculinities; intersections between gender, social class, race, ethnicity, and social exclusion; gender, education, and poverty in the context of globalization.

Gender and Education: Historical Perspectives on Contemporary Concerns

Published in 1792 *The Vindication of the Rights of Woman* was the first feminist philosophical work to reflect on women's condition in society. Inspired by the ideas of the French Revolution, Mary Wollstonecraft counterpoised ideas and discourses that constructed women as vulnerable, weak, and driven by emotions and passions. Women, she suggested can strengthen their mind and bodies through education and active involvement in the public spheres of life. Education in general, and women's education in particular, was central in Wollstonecraft's emancipatory project and it is here that she fiercely criticized Rouseau's ideas on the need for girls to have limited and differently oriented education than men. And yet Rousseau's ideas about the complimentary character of the education of girls set the theoretical framework that dominated the curricula and structures of women's education in modernity, while the feminist project of women's liberation has always revolved around the struggle for access to and equal opportunities in education. Of course many things have changed since the publication of *The Vindication of the Rights of Woman* and yet there are certain themes, concepts, and questions that are still at the heart of contemporary debates in gender and education.

The dilemma between equality and difference infused by social class prejudices and aspirations is a persistent issue in the debates that have historically shaped what has ultimately become the field of gender and education. Not only has the education of girls been perceived, designed, and institutionalized as different from boys, but also differences in girls' education have historically existed across social class divisions, although class has been an important axis of difference in boys' education as well.

Gender and Education: a Contested Field

While Wollstonecraft's work set the philosophical foundations of the theoretical debates within gender and education, it was in the literature of the second wave feminism that the field was constituted as a recognizable entity. Educational feminists in the 1970s and 1980s highlighted the importance of using 'gender' as a useful analytical category in the study of social inequalities in education. As a social construct 'gender' was a term that saved the problems of biological determinism that a focus on sexual difference unavoidably carried. Perceived as an effect of social construction, gender relations thus became not only the object of analysis and research of educational feminists, but also the target of feminist educational practices that were aiming to criticize and change them. This early body of literature was shaped by the idea of education as a site sustaining and reproducing the subordination of women in general and working-class girls in particular. It thus focused on the big themes of equality of opportunities as well as questions of representation and recognition. Among the most specific themes taken up, were the links between capitalism, patriarchy, and policy making in education; open and hidden practices of sexual discrimination and patriarchal structures in schools; as well as cultural representations of gender relations in the language, discourses, and curricula of schooling (see Arnot and Weiner, 1987). As it has been more widely discussed, there were both advantages and limitations in the different versions of the social reproduction theories, particularly in the way they theorized the role of masculinities and femininities not only in shaping class relations and gender inequality in schools, but also in opening up sites of resistance in the dominant culture of schooling (Willis, 1977). It was by attending to the subtle ways that young people negotiated the formation of cultural identities as active agents, albeit within the constraints and limitations of capitalism and patriarchy, that education eventually emerged as a site of both domination and resistance, a battlefield of fierce power/gender relations at play.

The Impact of New Formations in Gender Theories

The rejection of the simplistic division between 'biologically determined sex' and 'socially constructed gender' and the acknowledgment that gender as well as sex are cultural categories, discursively constructed but with real effects on women's lives, (Butler, 1990) have had a significant impact in

the theoretical developments within the field of gender and education. While equality of opportunities and feminist interventions in the curricula of school subjects and the structures of schooling remained important areas of concern, new questions also emerged around the effects of educational discourses and practices in the formation of gendered identities and subject positions. What has emerged as a thorny issue in such debates is the question of difference not in its Platonic configurations as opposed to sameness, but as difference per se. In this light, how can education feminists theorize difference without subsuming it to the norm, heterosexual or otherwise? Moreover how do the politics of difference work within the material and discursive conditions of schooling? It is within the context of taking difference seriously that current debates and concerns in gender and education have emerged and developed in a rich body of literature including among others, a dedicated journal, *Gender and Education*, a range of readers and handbooks (Arnot and Mac an Ghaill, 2006; Skelton et al., 2006) as well as a wide collection of monographs, edited volumes, and journal articles. What has to be noted is that the field of gender and education has specific geographies and histories, which have an impact upon the many theoretical, methodological, and policy-making differences within it.

Current Debates and Issues in Gender and Education

Gender, Subjectivity, and the Constitution of Identity within Neoliberalism

As already noted above, the field of gender and education has always been in dialogue with diverse traditions within social and cultural theory, particularly in relation to questions around identity, subjectivity, and the self. Such questions have taken a new momentum in the context of discourses around individualization and the neoliberal society. Here the notion of 'the reflexive self' has been influential in taking the field beyond the problems of the social reproduction theories and in opening up ground for theorizing agency and resistance within education, but it has inevitably posed its own limitations and constraints (see Francis and Skelton, 2009). In the context of such debates and theoretical concerns feminist scholarship in education has revisited the social construction of masculinities and femininities. Here insights from queer studies (Halberstam, 1998) have been influential in troubling the male/female binarism, bringing forward ideas about female masculinities or masculine femininities. What theorists in the field of gender and education have mostly highlighted here is how boys and girls learn and understand gender within 'communities of practice,' such as schooling, and therefore how teachers can intervene in the processes within which boys and girls learn and practice gender (see Paechter, 2007).

Intersecting Inequalities

'Intersectionality' is a theoretical and methodological framework introduced by Kimberle Crenshaw in 1989 as a way of analyzing socially constructed categories such as race, class, gender, sexual orientation, and disability among others, by viewing their interaction in creating extreme regimes of inequality, disadvantage, and oppression. Initially conceived as a psychosocial plane wherein multiple identities and experiences of subordination and exclusion meet and interact, intersectionality has become today an influential concept in feminist scholarship in gender studies in general and the field of gender and education in particular. Intersectionality is also a very useful framework within which the social construction of cultural identities can be seen and understood in much more comprehensive and efficient ways than in the 1970s and 1980s. Although gender is a crucial social axis of difference, it always intersects with other social categories of difference and is therefore always decentered, but without being subsumed by them. Through the prism of intersectionality, gendered inequalities in education therefore become more complex and less essentialized and the framework offers better ways of both understanding and fighting against inequalities in education (see Phoenix and Patiyama, 2006).

Gender, Racialization, and Social Exclusion

Black feminist though has had a significant impact in shaping problematics and thematic concerns in gender and education and in exposing the Eurocentric elements and Westernized discourses of earlier feminist theorizations in education and beyond (Hooks, 1989; Mirza, 1992, 2009). In the light of the social construction of race that critical race theories have put forward, there is a rich body of literature looking into the intersection of colonial discourses, narratives, and practices in shaping gendered and racialized identities in education in the context of racism, xenophobia, and new flows of migration. School failure and social exclusion have been identified as effects of racialization; what has also been criticized is the construction of stereotypes and prejudices around 'the black girl and boy' (Phoenix, 1987). Here again, intersectionality has revealed the inadequacies of simplistic binarisms, black/white, femininities/masculinities, working class/middle class, to name but the most obvious (see Ahmed, 2009). In this light, a new body of educational research has been formed focusing on questions of social exclusion of black and minority ethnic youth, particularly so in the urban spaces of contemporary global cities. Indeed an attention to both space and time has become an organizing axis in this dynamic body of literature, while the buzzworth of 'the risk society' has been challenged and problematized. What has also been highlighted is the gendered nature of the young people's agentic interventions in the discourses and practices that condition, but not necessarily determine their lives (see among others, Dillabough and Kennedy, 2010; Archer, Hollingworth and Mendick, 2010).

Gender, Class, Choice, and Emotions in the Education Market

New theorizations of the study of educational markets have led to important feminist analyses of marketization, wherein gender, education, and social class have been revisited in the light of intersectionality. In the context of analyzing market forces in their interaction with classed positions rather than classed identities, which have always been problematic vis-à-vis women, an interesting body of research has emerged within which new questions have been raised, linking family life, education, and the market. Beverly Skegg's (1997) theorization of how women live and produce themselves through social and

cultural relations has been influential here and it is exemplary of a field of feminists engaging with the ideas of Pierre Bourdieu (1977, 1984). Diane Reay's (1998) research is an exemplary case of the Bourdieu-feminism encounter in looking into gendered modes of parenting, particularly focusing on the role of mothers in the schooling of their children. The cost of educational success for middle-class and working-class girls is also a very interesting field of inquiries particularly focusing on psychosocial approaches in the field of gender and education (see, Walkerdine et al., 2001). This body of research has further opened up new grounds of inquiries in the field, which look into the importance of emotions and affects in girls' and boys' schooling and beyond (see Davies and Gannon, 2006).

Gender, Education, Poverty, and Globalization

Education feminists have examined gendered processes of globalization and the way they impact educational policies within global and local contexts. Gender, education, and global poverty have been at the focus of much international concern and have generated a cluster of both research and policy-making initiatives. But there is a gap researchers in the field argue between what theoretical frameworks and education policy discourses set out to achieve and what actually happens on the ground. More importantly there are differences between people's needs and issues raised by policies, and finally there is a difficulty in drawing conceptual and causal links between gender, education, and poverty. As a consequence there is a lack of any academic, professional, or policy language to deal with the social contexts of poverty, and gender equality is one of them, but also a tendency to blame individuals and more particularly the poor parent. What emerges as a need is for academics to operationalize important concepts such as intersectionality, so that new theoretical and methodological tools can emerge. What also persists as a need for theorists and practitioners in the field is to further criticize and deconstruct gender stereotypes and prejudices. The pressure of the market and the need to have satisfactory performance is also a stumbling block in the attempt to develop reflexivity and adequate language and policies to address problems emerging from the intersection of gender, education, and poverty. Working with teachers on the school level around issues of gender and poverty has been highlighted as a priority in this area (see Unterhalter and Carpentier, 2010).

The Question of Boys' Education: Critical Responses

It goes without saying that the question of 'boys' underachievement' has been a dominant discourse in gender and education, both in terms of theoretical engagement and in terms of addressing policy-making and pedagogical practices. Here the crisis of masculinity has been the overarching theme, with a significant body of literature revolving around it (see Connell, 2005; Martin, 2001; Mac an Ghaill, 1994). Although the problem of 'boys' underachievement' has become prominent both in policy reports and media coverage since the 1990s, scholars in gender and education have taken a more skeptical and critical approach. They have looked into the history of 'the problem' and have raised questions as to why it has become so prominent in late modernity. The question with boys has also been related to the problem of 'the feminization of schooling' and the importance of male teachers for boys' education (see Epstein et al., 1998). The boys' question has also marginalized some important issues with the education of girls today, including teenage pregnancy, sexualization of girls, and bullying both in friendship groups and through the new social media, or what is now called, cyberbullying. More importantly, the problem with boys is underpinned by a set of discourses grounded in the assumption that gender equality in education has now been achieved and that girls have been excessively empowered at the expense of boys. It is in the context of the current economic crisis and massive unemployment both for men and women that 'blaming girls' has become a populist discourse that has been uncritically accepted in the field of educational policies today on a global level, although with local transmutations and versions (see Ringrose, 2012).

Abstract

The rate at which economies grow and the contribution that education in both formal and informal settings makes to such growth has been a subject of considerable study and debate going back to the founding of economics as a social science discipline. Numerous models and approaches have been tried and some progress has been made in understanding the complexities of this relationship.

The manner and rate of economic growth among nations and their causes has been a topic for theory building, speculation, and investigation since the inception of the discipline of economics. Early economists such as Adam Smith and John Stuart Mill recognized that there must be a link between education, broadly defined, and economic growth. Explorations of the nature of the linkage did not seriously get under way until the early 1960s with the work of American economists Theodore Schultz (1961) and Gary S. Becker (1993), who developed a theory of human capital (the total set of skills, abilities, ideas, and health residing among individuals within a society, organization, or other unit of analysis that are the results of productive investments in human beings) formation and then sought to analyze the rate of return of investment in education and training. The last half of the twentieth century has abundantly documented that linkages exist but that they are neither inevitable nor straightforward in their relationships and effects. Early naïve theories of human capital that proposed strict linear relationships between formal education and economic growth at both the individual (micro) and societal (macro) levels have now been abandoned in the face of overwhelming evidence that only a few and modest direct relationships can be obtained no matter what definition or method of analysis is used.

Defining Growth and Education

Reasons for this maze of complexity are not hard to find. First we have to consider that when we speak of both 'the economy' and 'economic growth' there are many different ways in which they can be conceptualized, bounded, and measured. Changes in Gross National Product (GNP), Gross Domestic Product (GDP; the total final output of goods and services within a given country's economy that are produced within its territory for a given period of time, without regard to where the owners of such output reside), import/export ratios, unemployment rates, and various indices of economic activity are just a few of the many ways, individually or in combination, by which both an economy and/or economic growth can be operationally defined. To take but one telling example, it was estimated using disparate data sources and expert advice that illicit criminal activities and money laundering account for around 3.6% of global GDP, which equated to $2.1 trillion USD in 2009 according to the United Nations Office on Drugs and Crime (2011). This illegal 'economy' is a significant share of the economies of many nations but is unaccounted for by standard models and studies of both economies within particular countries and the economic growth occurring in those nations.

The means by which rates of growth are calculated can also have a marked impact on whether 'growth' is discerned or not (e.g., year-to-year change, rolling averages, decade-to-decade change). Any growth inevitably occurs within convoluted national, regional, and global contexts that includes substantial changes over time in factors such as population growth, immigration patterns, human capital, technological innovations, structural unemployment, evolving taxation and accounting policies, trade agreements and tariffs, 'hidden' or 'black market' economies, regulatory environments, and political leadership. The degree to which these changes are measured and factored into economic growth models to create 'value-added' or 'adjusted' rates varies considerably among economists and particular schools of thought within which they work.

We also need to consider that as the world economy changes over time, particular sectors of national economies may alter significantly. Increasingly in many nations, applications of knowledge and information drive economic indices of productivity rather than material goods. Changing production patterns that emphasize customization and just-in-time delivery have significantly altered both our conceptions and means of economic growth. Large corporations within the highly interdependent global economy often have worldwide revenues that exceed the GNP of many nations; Walmart, the world's largest corporation in 2010 had global annual revenues exceeding by several billion USD the GDP of Norway – the world's 25th largest economy that same year. These global corporations disperse and shift their corporate assets among many countries for complex reasons rendering quantification of economic growth within particularly smaller countries in any kind of reliable manner increasingly both less precise and more difficult.

Sitting behind every econometric model, such as Nobel Prize winner Robert M. Solow's neoclassical growth model (Solow, 1956), is reality itself – an entity vastly more complex than any of these models which have been created as useful yet greatly simplified abstractions to attempt to elucidate aspects of this much more convoluted, intricate, and highly dynamic environment. At a macro-level, we know that many, if not most, of these models are crude approximations and quite a few are even known explicitly to be wrong in their underlying assumptions (now thoroughly falsified). One of the continuing problems in economic modeling is the frequent failure of the designers and users of such models to explain adequately to others the models' underlying assumptions and their reasonableness, the degree to which models do or do not represent reasonable attempts to mirror critical aspects of the real economies they are intended to describe (at least in part), the structure of the models themselves (i.e., how do they work?), how the chosen model compares in performance to competing models, and what are the important unknowns that the selected model does not address (Schlefer, 2012).

Still further complications arise when a particular model of economic growth (with its attendant assumptions and foci) is analytically and econometrically related to education. 'Education' is a broad concept that includes a variety of subcategories or sectors. The 'formal' system would include primary, secondary, college/university, and certification forms of education (e.g., secondary education equivalency examinations, specialized training programs, and examinations that lead to industry-recognized certifications). The formal system can be further subdivided into public and private spheres. Economists and other researchers generally have scant information about the private sector of education. In some nations or special administrative regions, private schooling accounts for better than 90% of all students enrolled in schools; within Organization for Economic Co-operation and Development (OECD) nations, the percentage of students enrolled in nonpublic schools can range well above 50% (OECD, 2011). Virtually all models of economic growth include substantial data available from the public sphere and usually only very modest amounts from the private sector. In most jurisdictions there are no explicit requirements or enforcement measures for regular data collection among private schools. All too frequently when people study the relationship between economic growth (however conceived, measured, and modeled) and education, this critical matter of missing data is forgotten.

Educational credentials and how they are obtained vary enormously across the globe. Even within OECD nations there is much more variation that is commonly realized along many dimensions. For example, the number of years of formal schooling for which more than 90% of the eligible population are enrolled ranged from 10 to 15 years, with a mean of 13 years (OECD, 2011). The number of specific academic 'tracks' into which students are grouped and the kinds of experiences they receive within their respective tracks varies greatly, even within the same nation – let alone across nations. It is well to remind ourselves when viewing a particular econometric model that frequently these variations are 'lost' in an aggregate construct that lumps them all conveniently in the same category, despite differences that would be both obvious and important to even a casual observer.

Formal education in most nations can also be divided into academic and vocational/technical in terms of its chief focus and once again differing results are seen when considering the impact of these different forms of education on the economy. The percentage of students enrolled in vocational programs within OECD nations, for example, ranges from a low of 9% to a high of 69% (OECD, 2011). This means that when a construct is created that just uses 'education' as measured by a grade level attained or a school leaving certificate (diploma) issued, it misses one of the most important differentiators among various groups of students' learning experiences and their acquisition of various skills and leaves unexplained the contributions that different forms of education within secondary schools, in particular, might make toward both individual financial growth prospects and economic growth (see Malamud and Pop-Eleches, 2010; Vignoles et al., 2011 for two important exceptions).

An 'informal' education sector also exists in nations around the globe. It embraces noncredit forms of education and peer-learning systems (operating without the knowledge of management) that occur on the job and within cultures generally (e.g., evening 'courses' offered to the local community hosted by a local secondary school but having no formal relationship to credentialing or degree-granting institutions or 'clan-type' organizations that provide informal learning exchanges for their constituents). There also exists the arena of job-related training or education which can take the form of job-embedded education (internships, apprenticeships, union-led training, formal company programs) and industry- or state-led training (e.g., vocational/technical education for adults) or retraining schemes, often conducted under the guise of either economic competitiveness or ameliorating the effects of structural unemployment. Informal learning has been estimated to represent in some countries more than 70% of all work-related learning and among students within OECD nations who did not complete some form of upper secondary education, nonformal learning accounts for 50% of their reported learning. The percentage rises (rather than falls) to 65% for those OECD students who obtained an upper secondary certificate – a reminder that even among the most well-educated students, informal learning plays a large role in their acquisition of further knowledge and skills (OECD, 2011). This informal learning presumably acts as a substantial moderator for whatever earlier formal education was undertaken. Once again, many economic models fail to account for the major role such informal learning plays, and its influence on productivity and economic growth more generally is largely underexplored. It does appear that investments in these types of informal education schemes, amounting to billions of USD per year in many nations, are particularly difficult to optimize owing to the dramatic influence of economic policies within competitive markets. Success requires a close match between labor market conditions and the kinds of training received.

Adult basic education (for those who did not graduate from secondary schools) and general efforts to teach literacy must also be considered as important sectors of education that generally operate in isolation from the world of primary and

secondary education. The economic effects wrought by adult education are difficult to measure and vary considerably among nations owing to other factors. Adult basic education, for example, is fairly large even in highly industrialized nations such as the United States and may be a much larger sector than formal education in some lightly industrialized nations. Finally, we must recognize that at the individual level there is much additional nonformal education that occurs as a person accumulates life experiences, reads, interacts with others, and thinks about things as they traverse the life course. The cumulative effects of these highly personal forms of education are unknown in their impacts upon economic growth.

Models of economic growth that seek to document the impact of 'education' usually focus on one or at most two of the above subcategories and frequently employ different data sources and use different definitions and rationales for parsing the data sources. Not surprisingly, they frequently come to dramatically different and frequently contradictory conclusions that arise due to the measures for economic growth adopted, the methodology employed, the scope of the inquiry, the data sources consulted, the ways the data are sorted before analysis commences, the meanings inferred from the analyses, the manner in which unknowns are identified and handled, and a myriad of other factors (Wolf, 2002, 2004).

The Continuum of Development

Further complications arise when moving up and down the continuum of highly industrialized, information-intensive economies and minimally industrialized, information-modest economies (a growing North–South divide on the planet). Economic growth models generally focus on the capacity of a national economy and on measures such as global market share, employment in wage-related activities, income contributions (personal and corporate taxes), redistribution schemes, and other factors that embody within them an implicit belief that these are the proper measures for 'growth' and 'progress' for all cultures, peoples, and nations. Movement 'up' the development continuum to greater industrialization and an intensification of the role of information within the economy are seen as valuable and essential for every nation. This view elevates economic considerations as defined principally by economists who live in particular types of economies into a global standard against which all nations are measured. It ignores noneconomic factors such as population growth (e.g., overly expansive growth and a failure to replace the current population are both generally frowned upon by economists but may be viewed positively by significant segments of certain societies); political considerations (e.g., socialist regimes may view economic goals differently from the majority of economists who work within capitalist frameworks); sociocultural milieus (e.g., individual and group behaviors and class structures); and issues such as fertility, life expectancy, and child mortality.

Economists who have looked at some of these issues in relation to 'developing nations' routinely suspect that current approaches probably underestimate how education improves social welfare and increases economic growth. Additional data sources not generally accounted for in research paradigms include the hidden economies revolving around the informal labor sector, black markets, and other exchanges of goods that are not quantified or quantifiable in many nations of the world. For example, it is estimated that only about half of the GNP in developing nations is comprised of the share of earnings from labor versus a range of 60–70% in highly industrialized nations. Some economists have recommended that dualistic models be created to address adequately the many extremes of the development spectrum. Others have suggested that really four distinct types of economies can now be found among developing nations: (1) newly industrialized nations in Asia, (2) relatively highly educated Latin American countries, (3) large continental economies such as India and China, and (4) marginal rural economies found in Asia, Africa, and Latin America.

A number of disparate findings have emerged when viewing the impact of education on earnings along the development continuum. Higher average levels of formal education are frequently associated with higher earnings in most highly industrialized nations, although notable exceptions are sometimes seen in some nations of Eastern Europe and Russia (Pritchett, 2001; Bassanini and Scarpetta, 2002). Nations at the other end of the spectrum generally demonstrate negative associations with education at university level once educated labor is no longer scarce. This is probably due to the fact that the expansion of the educated labor force has far outstripped the supply of jobs requiring such high levels of formal education and this disequilibrium exacerbates civil unrest. Oversupply has led many economists to recommend that postsecondary education be scaled back in many developing nations and these resources be targeted to primary education interventions. Investments in the education of women (a key source of inequality in many countries) and in general education (as opposed to vocational education) yield returns equal to or better than their alternatives, although once again there are notable exceptions based on differences in economic policies, social structures, and the distribution of education (Park, 2006; Altinok, 2006; Barro, 2001).

Human Capital Theory

Economists classically view labor, land, and capital (human or otherwise) as the three principal inputs into production. Studies of the contribution of education to economic growth have been one line of investigation within the human capital dimension – often held in tension with inputs from the other two sectors in complex multidimensional models to tease out the residuals that can be 'explained' in a statistical sense by education as defined by the researcher. These 'growth accounting' (A technique pioneered by Nobel Prize winning economist Robert Solow (1956) to measure the amount that various factors contribute to the economy. The 'unexplained' portion ('residual') is attributed to the influence of general technological progress within the given society.) models have generally shown a fairly modest effect of education on economic growth ranging from as low as 1% to highs of around 10% since the 1970s. Perhaps not surprisingly, returns from primary-level education (basic literacy and

numeracy) are generally found to be much higher than for other levels and the decline can be steep as one ascends the levels of formal education.

A significant correlation emerges between education and growth. Education can be thought of as the stock of human capital (measured either by the flow of spending on education or by level of educational attainment). If we separate educational attainment on the basis of the educational level attained, this analysis (Aghion and Howitt, 2008) eliminates the 'problem' of the weak relationship traditionally observed between growth in OECD countries and the insignificant impact of education as measured by mean national educational achievement (cf Krueger and Lindahl, 2001). In particular, this decomposition approach not only finds a stronger relationship but also suggests that tertiary education more strongly impacts growth in the economies closest to the world's technology frontier (i.e., the technological global stock of knowledge available in all sectors and all countries). Technological prowess this close to the border reinforces the positive effects of higher education on a country's ability to innovate. Once again it is important to remember that tertiary programs even within OECD nations vary greatly in their composition, student access (with rates ranging from 70% to just 35%), and the actual knowledge and skills on which they focus (OECD, 2011). Whether this particular finding will hold up as more detailed studies are undertaken that look into these variegated realities remains to be seen. It also appears that primary and secondary educational attainment seems rather more to impact on the growth of economies located far from the technological frontier, strengthening the ability to imitate or implement existing technologies (Acemoglu et al., 2006; Vandenbussche et al., 2006).

A working assumption that underlies virtually all human capital approaches going back to Nobel Prize winner Gary Becker and colleagues (Becker et al., 1995) is that people will invest at an individual level up to the point where they believe they are going to realize a full return on their investment. This is often driven by a belief that there are certain fundamental skills that one must acquire in order to compete or advance successfully in the labor market. (It is important to note that costs subsidized by the state or other entities rather than the individual, routinely result in most students choosing to go for a higher level of education or credential than they would elect if they had to bear the full cost themselves.) Schools serve as a powerful socializing influence both in reinforcing the value of education and in shaping the kinds of educational experiences and expectations that people hold (Godoy et al., 2005; Seng, 2011). In many societies, schooling serves as a modernizing function whereas in others (e.g., certain Islamic societies), it may serve to restrict impulses frequently associated with modernization or open capitalist societies (Obst and Kirk, 2010).

Formal education frequently acts as a filter or a screen that determines a threshold level that a job applicant must meet in order to be considered for an open position. One of the many reasons why there are such modest direct relationships between education and economic growth or even education and earning in a narrow sense is that market supply has a bearing on the level of education deemed minimally acceptable by an employer. In times of ample supply of applicants, employers often require a much higher level of education as a key screening tool. Adjusting education supply functions in the light of these changing demands in order to increase economic productivity is both conceptually and politically difficult and is generally discouraged. In part, this is because employers and policy makers recognize that education helps positively shape a variety of other aptitudes, dispositions, and motivation critical to work success. It is important to note also that wages are affected by many other factors extrinsic to employees and employers, such as taxation, price controls, inflation, and state and local policies and regulations. For these reasons, the strong form of the screening hypothesis that argued that higher levels of education signal higher wages over one's entire career is no longer viewed as tenable. A weaker form of the screening hypothesis that views credentials and higher levels of formal education as a filter at the initial hiring stage with accompanying early wage differentials is generally accepted. Competing theories about the operation of labor markets have produced divergent explanations for why educational attainment and levels of lifetime earnings generally hold over time in many industrialized nations. It has been amply demonstrated that holding the same level of education does not serve as a reliable predictor of earnings, undoubtedly due to other factors such as race, gender, ethnicity, ability, and social background. Women, for example, within OECD nations have an average total return (net present value) gross earnings premium that is $100 000 USD less than men – despite the fact that they have the same educational attainment or in many OECD countries, higher educational attainment than their male counterparts (OECD, 2011).

This line of research suggests that it is the highly developed economies relatively closer to the technological frontier which benefit more from higher education because they are better equipped in what is most important for growth when near this boundary (Araya and Peters, 2010; Peters and Bulut, 2011). In particular, these economies are relatively well endowed with highly skilled labor, which contributes relatively more to productivity growth when it is used more for innovation than simply imitation. In this vein, Oded Galor and Omer Moav (2000) show that human capital can accelerate technical progress, since it is more adaptable to new technologies. Similarly, developing economies located farther from the technological border will benefit more from primary and secondary education since they are relatively better endowed in what is important for growth when you are farther away from it, namely the low- and medium-skilled labor that contributes relatively more to productivity growth that is used more for imitation instead of innovation (Vandenbussche et al., 2006). The intuition behind these various proposals is based on the Rybczynski theorem, a by-product of the Heckscher–Ohlin model of international trade. Tadeusz Rybczynski (1955) noted that when a particular factor's presence is introduced into an economy there is a resultant increase in the amount of products that utilize that factor in production with a resultant decrease in the output of products that utilize other factors. These changes within economies stimulate regional trade as the supply and demand for both factors and products change dynamically (Rybczynski, 1955). Eli Heckscher and Nobelist economist Bertil Ohlin (Flam and Flanders, 1991) noticed that countries emphasize within their

economies products for export that are produced from more abundant local inputs and import products for which local production would draw upon scarce resources. Flam and Flanders (1991) postulate that an increase in the supply of an input into a sector where it is used most intensely tends to increase disproportionally the output from this sector and simultaneously prompt a decline in the output from another sector.

This reasoning suggests that for any given country, even more important than its total stock of human capital in explaining growth, is the composition of its human capital and its proximity to the world technology frontier. These factors are most determinative for its growth potential. In terms of growth, the full value of a nation's comparative advantage is based on their endowment of labor supplied by an education system that is aligned with these particular goals. Advanced economies can thus strengthen or improve their comparative advantages by prescribing a policy of investing in higher education and research to increase the potential of the highly skilled workforce they are relatively better situated to deploy (Black and Smith, 2006; but see Moretti, 2004 for a cautionary study). This will have the dual effect of increasing the marginal productivity of their highly skilled workforce and enhance their productive path of specialization toward goods and services with high-added value, i.e., toward a knowledge economy that accentuates innovation and knowledge invention (Krueger and Kumar 2004). Economies with unequal initial endowments in human capital grow at different rates, influenced in part by the degree to which their public policies are committed to public support of the education sector focused on provision of advanced education and training in order to avoid the trap of underdevelopment and promote high growth (Azariadis and Drazen, 1990). It is against this background that emerging economies attempt their technological catch-up (i.e., reducing the distance to the technological frontier). While these strategies are being pursued by emerging economies, the technological frontier continues to move inexorably forward within advanced economies, propelled by the powerful synergistic relationship between education and economic development at the existing technological frontier. There is little evidence that the gap is closing directly but indirectly it may close due to other factors, such as changes in population pyramids which may weaken some advanced economies.

The importance of technological catch-up for developing economies raises the fundamental question of the impact of the cost of education or other barriers on access to education (e.g., in the form of social and ethnic barriers, inadequate public investment in education, and imperfections in the credit market) on economic growth (Berik et al., 2011). People continually assess their prospects for future earnings within the labor market, as compared to the relative cost of their education, and expected future gains in the form of higher wages. The adoption of new technologies requires that we replace unskilled labor with skilled labor, which in turn drives a higher cost for education provision, which results in higher wages for skilled workers and increases in the cost of adoption of new technologies. Barriers to education are, therefore, disproportionally detrimental for developing economies that cannot provide the relatively high wages of skilled workers, thereby increasing the risk of underdevelopment traps (Conrad, 2009; Zeira, 2009). We can thus explain the differences between economies in terms of their technological level of development in part by the differences in the cost of education. When education is largely in the public sector, as is the case in most developing countries, public policy can significantly increase the potential of the positive impact of education on growth by reducing the cost of education. It should also be clear that developing economies must find ways to finance a good public education system, which unfortunately is often not the case given the many challenges and constraints they often face (Kern, 2008; Thirwall, 2011).

Human capital theory has been substantially modified from its early days when considering the impact of education upon the economy. Understanding of human capital has expanded exponentially beyond education per se to embrace issues such as age distributions within given nations, rurality versus urbanity, and threshold factors to economic growth in some nations such as basic health, sanitation, housing, water supply, and nutrition. The modest claims for education's impact on economic growth advanced today are a reflection of both the complexities involved and what Theodore Schultz (1961) has called 'adjusting to economic disequilibrium.' The problems associated with the human capital approach have led to several competing theories about the relationship between education and economic development. One theory takes an institutional approach and argues that supply and demand in education is shaped by larger social behaviors within the society. It is these social conditions, rather than education per se, that is influential on economic growth. A second approach focuses on labor market segmentation and internal labor markets, which in turn influence both education and economic growth.

The existence of institutions and appropriate economic policies promotes regulatory consistency and the necessary stability for the protection of property rights (i.e., protecting innovations against imitation). When these features are coupled with a highly performing education system that increases the pace and efficiency of R & D activities and the continual supply of skilled labor, this combination improves long-term growth. The relationship between institutional foundations and educational growth seems particularly crucial in the case of economies in a technological catch-up situation. While technological catch-up allows poorer economies to grow as rapidly as their richer counterparts, this recovery depends on innovation for which a good legal environment and quality education are both fundamental (Borota, 2012; Glaeser et al., 2004).

A comprehensive causative model for economic growth embracing all sectors of education has proved elusive (Blundell et al., 2005). While the general premise of a link between education and economic growth appears sound, the complexities associated with explicating the exact nature of this premise challenge the best theories and economists.

Education and Employment

Ulrich Teichler, International Centre for Higher Education Research (INCHER-Kassel), University of Kassel, Kassel, Germany

Abstract

The relationships between education and employment are determined not only by the function of education to prepare learning for subsequent work tasks and other life spheres, but also by the fact that education selects: in an educational meritocracy, the monetary resources and the social recognitions are largely determined by the individuals' level of educational attainment and their competencies fostered during the course of learning. The levels and the types of education, however, never are closely 'matched' to professional positions and job requirements. Imperfections are unavoidable, because individuals have to be trained to cope with imperfections and to be able to change employment and work themselves proactively. National traditions of education and training persist to a certain extent according to which education might vary from being understood as the general foundation for professional learning on the job toward being understood as specific training for respective jobs. The dramatically rapid expansion of education is interpreted as serving the needs of the knowledge society as an oversupply which might be absorbed and as stimulating changes of the system of employment and work.

The Professional Relevance of Education

Education dissociates the learner physically from work in early years of the life course in order to prepare in a rational way for coping with diversity of work and life tasks. Education has a qualifying function and a status-distributive function for economy and society and is among various factors determining graduates' careers. Imperfect links between education and employment are due to limits in the identification of job requirements, occupational dynamics, indeterminate work tasks of the highly qualified workforce, planning gaps, diverse curricular concepts, and growing importance of lifelong education, whereby diverse value judgments come into play. Research on the relationships between education and employment is strongly influenced by a few economic paradigms, notably the human capital approach. But various other areas of research are relevant as well: labor market research, vocational education, educational sociology, sociology, and history of the professional, sociology of mobility, etc.

Views vary as regards the extent to which expansion of education was stimulated by a growing demand for highly qualified labor or the extent to which educational expansion itself triggered initially an absorption of more highly trained persons on the labor market and subsequently notions of increased demand. Over the decades, unemployment rates were lower in most economically advanced countries the higher the level of educational attainment was. Higher education graduates continued to earn on average of these countries twice as much as compulsory school leavers, and investment in education surpassed the interest rates of business capital in the majority of industrial societies.

Public debates had put a stronger emphasis on the vertical than horizontal 'match' between education and employment. A trend toward higher levels of education than necessarily required by the employment system is obvious, but terms such as 'overeducation' neglect the frequent and innovative use of competencies, even if the position does not necessarily require a graduate. In the 1970s, concern grew about unemployment and precarious employment of youth. The higher the educational attainment, the lower is the risk of becoming unemployed. As youth unemployment is relatively low in countries with apprenticeship training systems, the German approach was most popular in the late 1970s. In the 1980s, the Japanese model of a combination of general vocational education and initial in-company on-the-job training was most widely appreciated, while since the 1990s, a search for new mixes and the appreciation of diverse models prevails (see Cedefop, 2009). Transition from education to employment, a focus of attention since the 1990s, is now viewed as a process taking up to 10 years of search, additional learning, etc. Transition processes and their results are not merely differently determined by varied educational approaches, but also by factors such as credentialism, impact of sociobiographic background, measures of counseling and placement, and by efforts on the part of graduates to improve their employment prospect through diligent search, smart tactics, and the demonstration of talents not rewarded in education. Education became singly the most important determinant of career in the nineteenth and twentieth centuries. Available research, however, suggests that other factors should not be underrated and that education increasingly becomes a precondition of career success in the process of educational expansion, and income differences might be based to a decreasing extent on level of educational attainment once a knowledge society is realized with more than half of the population having attained tertiary education (OECD, 1997).

Schooling is a social mechanism which, as a rule, dissociates the learner physically for a certain life period from the regular world of work and other life spheres. This is undertaken in order to prepare learners in a more rational manner for coping successfully with the diversity of work and other life tasks through explanations, rules, general reasoning strategies, etc. The more efficient the industrial society or postindustrial knowledge society became in producing wealth, the more the education system and generated competencies contributing to

the production of goods and services expanded. Regarding the world of work, education has:

1. A qualifying (in the French and German connotation) function of fostering the cognitive and possibly affective and senso-motoric capabilities which might be useful to cope with job tasks.
2. A status-distributive function: the level of 'educational attainment' determines to a certain extent the monetary resources and the social recognition which will be available to individuals in their subsequent life; for education is a powerful factor – and has increasingly become so over the nineteenth and twentieth centuries – in opening up or closing access to prestigious occupations and providing the means for professional achievement and thus to remuneration and socioeconomic status.

These basic functions are undisputed. However, it is generally assumed that education is bound to be imperfect in preparing for the world of work, partly because rational learning through dissociation from practice has its price in less direct preparation for occupational tasks and because education is expected to serve broader functions. Also, other factors contribute to professional success, e.g., sociobiographic background, genetically determined abilities, specific dynamics of credentials, processes of transfer from education to employment, and finally lifelong learning and personal development. Thus views vary as regards the actual ways education is and ought to be shaped as well as the actual impacts learning has and ought to have on subsequent employment and work. However, recent years were characterized by an increasing public expectation that education serve more visibly the preparation for work, as the growing popularity of the term 'employability' suggests (see Knight and Yorke, 2003).

Imperfections and Limits of the Linkages of Education and Employment

Even if education was expected to be closely geared to the 'requirements' of the employment system and even if there were not any particularistic social factors at play there are obvious imperfections and uncertainties which make close linkages unlikely (see Teichler, 2009). Available research and past debates for instance pointed out the following issues:

1. Occupational dynamics: The employment system is very dynamic in terms of changes of job tasks within given occupations, and most people have to expect occupational mobility in terms of employers or occupations as a consequence of growth and shrinkage of the various occupations. This challenges the view that precareer education and training should prepare only for a very specific bundle of job tasks.
2. Indeterminate work tasks for a highly qualified workforce: The higher the educational level needed for a certain occupational area, the more difficult it is to identify the competencies actually required.
3. Planning gap: There is an unavoidable time gap between the identification of new job assignments and the provision of respective competencies on the part of school leavers and graduates, because years are needed for the revision of curricula and the actual 'production' of new graduates.
4. Generalists' versus specialists' paradigms: Views vary among experts – and among employers as well – regarding the extent to which education should be general or specialized according to areas of knowledge or occupations.
5. Emphasis on vocational education vs. recurrent education: Finally, views differ similarly on the extent to which the growing role of lifelong learning might reduce the need for precareer vocational or professional education and training, on the change of learning abilities over the life course, job requirements in different career stages, and the economic and social conditions for lifelong learning (cf Schuller and Tuijnman, 1999).

In all societies, controversies can be observed as regards the extent to which education is viewed as instrumental in securing the individual's and the society's economic success. There are also strong national differences with respect to four areas of values.

1. An 'educational meritocracy,' i.e., a strong impact of educational attainment on subsequent career, seems to be realized to a different extent in economically advanced countries, most strongly in Japan, whereas lifelong opportunities for counteracting those links are emphasized in the USA.
2. A general or specific approach of education and training: Where a generalist's view prevails, for example in Anglo-Saxon countries and in Japan, specialized training tends to be viewed as 'narrow' both in terms of restraining professional flexibility and personality development. Where a specialist's view dominates, notably in France and to a certain extent in Germany, the acquisition of specific knowledge is considered as a process of exemplary in-depth learning which ensures substantial transfer to other areas of expertise, and is viewed as compatible with a broadly cultured personality.
3. Concepts of employment and work-related identity: In France and Germany, employment and work are generally expected to be a major force for individual identity. This tradition has reinforced a high level of pride in skilled workers in Germany. In contrast, sense of affiliation to one's own employing organization tends to be viewed as a major source of identity and pride in Japan. In the Anglo-Saxon tradition, identity linked to work seems to be a phenomenon confined to high-level occupations, as the distinction underscores between (high-level) 'professions' and other 'vocational' areas.
4. The role policies actually play and should play in shaping the relationships between education and employment: In the Soviet Union and affiliated countries, strong efforts were made from the 1950s through the 1980s to plan education according to the perceived demands of a planned economy. In the USA, faith in the self-regulatory forces is most widespread as far as educational preparation for employment and work in a market-driven economy is concerned. In European countries, different degrees of macroplanning and steering of education are considered essential in order to strike the balance between economic and other social and cultural rationales of education in a predominantly market-driven economy.

The different values are so pertinent for the actual links between education and employment in the respective societies that interpretations of research findings and discussions of their policies are most likely to reinforce national characteristics of education–employment relationships.

Trends of Educational Attainment

Expansion of education seems to have been a perennial trend since World War II. On average, about one-third of the adult population in industrial societies had at least some upper secondary education in 1960; this proportion reached two-thirds in the late 1990s (OECD, 2000) and increased to 73% in 2009 (OECD, 2011).

From the late 1950s through the early 1970s, optimism prevailed that the economy requires a substantial increase of labor with advanced levels of education and that educational expansion is instrumental to economic growth. Comparisons focused on general and full-time schooling, thus neglecting vocational training. Accordingly, full-time enrollment rates of 17 year olds were 86% in the USA in 1970, about three-quarters in Canada and Japan, but only ranged in Western Europe from about 60% to about 20% (OECD, 1977).

The 1973 'oil crisis' was a turning point of the political mood, and concern about unemployment in general began to dominate over problems of employability of youth and potential mismatches between education and employment due to an oversupply of labor with higher or other advanced levels of education and training. At that time, the OECD began to include part-time enrollment and apprenticeship training into their figures of upper secondary enrollment, thereby observing an average increase of the secondary education graduation quota from about 60% in industrial societies around 1970 to more than 80% in recent years.

Similarly, the proportion of the respective age group completing tertiary education (graduation rate) successfully increased from about 10% on average in economically advanced societies around 1970 to about half end of the first decade of the twenty-first century. A comparison of the educational attainment of the adult population (Table 1) shows that the differences by age are small in the USA, where the major expansion of enrollment took place before the 1970s, and high in Spain, where educational expansion is most pronounced in recent decades.

Table 1 Percentage of population from select countries having attained at least upper secondary and tertiary education, by age group 2009

Income Differences by Education

In all societies, educational attainment and income correlate. In European OECD member states, for example, those with upper secondary education earned on average in the 1990s about 1.3 times, those with nonuniversity tertiary education 1.5 times, and those with university-level education about twice as much as persons without upper secondary education (see OECD, 2011). Altogether, income differences by level of educational attainment have declined somewhat over the decades although not on average since the 1990s. Variations across countries cannot fully be explained by patterns of supply and demand; other social factors come into play which contribute to varying income inequality.

Calculations based on the human capital approach show that individual returns for higher education vary between countries from less than 5% to more than 20%. In some countries they surpass the interest rates of business capital, whereas in others they remain below that level.

The 'Match' between Education and Employment

The extent to which educational qualifications match the employment demands is a frequent topic of debate. One tries to establish – both for recent graduates and the total labor force – whether qualifications correspond to the occupational structure

1. horizontally (links between subjects and occupational categories) or
2. vertically (appropriateness of the level of education to the occupational status).

Altogether, concerns about a horizontal match are more pronounced in countries emphasizing specialization in education and employment than in countries considering education predominantly as a general preparation. They tend to be more pronounced as well regarding higher levels of education than lower ones: A substitution of a car mechanic by a baker seems to be more acceptable than that of an engineer by a chemist. But more leeway for substitution exists than expected. For example, the fact that about half of the Germans having undergone an apprenticeship training are employed

5 years later in occupations not closely linked to the type of training does not tend to be considered as a major wastage, but rather as an indicator that in-depth specialized vocational training fosters substantial potentials for flexibility and transfer of skills.

More attention has been paid to problems linked to possible vertical mismatches. In the 1960s, concern was frequently voiced that countries with a low proportion of the population with advanced education might fall behind the others with respect to economic growth. From the 1970s through the 1990s, in contrast, the controversies on the agenda concerned whether a trend toward 'overeducation' or 'overqualification' could be observed. During the 1990s, a mix of concerns about overeducation in some areas and lack of competencies in other areas, e.g., qualifications required for new technologies, was prevalent in many countries.

'Overeducation' and in some cases 'undereducation' was analyzed with the help of various measures:

1. Educational and occupational statistics seem to suggest that the expansion of advanced levels of education clearly surpassed the demand of the employment system.
2. Employers' expectations similarly tended to support the idea of substantial increase of 'overeducation' in the 1970s and 1980s, though they also point out lack of competencies in some domains.

Surveys of former students also show a higher frequency of education seemingly surpassing the level of job requirements than that of 'undereducation,' but they indicate that many graduates make use on the job of the higher level of competencies.

The progress of research notwithstanding, the issue of 'overeducation' seems to be perennial, because the tensions do not fade away between often steep occupational hierarchies and a relatively open access to the highest levels of education. However, concern tended to be voiced less dramatically in the 1990s than in the 1970s (e.g., Büchel et al., 2003; Teichler, 2009). This might be explained by widespread expectations that a 'knowledge society' is likely to emerge. Also, research has shown that most persons seemingly overqualified acquired a position only slightly lower than they had strived for.

Education, Unemployment, and 'Employability'

Youth unemployment and various modes of precarious employment became a major concern in most industrialized societies since the mid-1970s and in most developing countries for long periods. The unemployment quota among youth is substantially higher than that of the total labor force in most countries. Also, in most industrial societies, the higher the unemployment quotas are, the lower is the level of educational attainment. OECD calculations made in the late 1990s suggest that Europeans trained below upper secondary education have to expect 4 years of unemployment over their life course, those trained on upper secondary education somewhat more than 2 years, and those trained on tertiary education level somewhat more than 1 year.

This led to growing attention to the education of persons not achieving advanced levels of education, called for example, 'the forgotten majority' or the 'forgotten half.' A discussion was triggered as to whether an expansionist education policy could strengthen the employability potentials of young people and whether certain types of education and training were more successful than others in preparing youth for the world of work.

Various models were suggested to classify modes of vocational education and training on secondary education level (cf Tessaring, 1998). During the late 1970s, the apprenticeship training model (Lutz, 1994) became popular in international debates, because the youth unemployment rate in Germany and neighboring countries was not substantially higher than overall unemployment rates. During the 1980s, the pendulum of debate swung in favor of a general approach of vocational education combined with initial and further on-the-job training within the employment system, as customary in Japan.

Efforts were also made to increase educational and training opportunities in countries previously characterized by a low enrollment rate at the upper secondary education level. Recently new mixes of education and work experience have emerged without any single model being regarded as clearly superior (see Cedefop, 2009). Moreover, concepts of defining results of education and training in terms of 'competencies' gradually softened the dichotomic notions of education and training (see Blömeke et al., 2012).

Transition from Education to Employment

In the 1990s, increased attention was paid to the processes of transition from education to employment. An OECD study defined transition as a period of up to 10 years when youth might be searching for a satisfying and well-paid job, orientation and efforts to supplement competencies might interact, and employment opportunities might differ from those for the older workforce (Werquin et al., 1997).

Part of the respective research focuses on the job start as a major indicator of the relationships between education and employment. Other studies analyze the speed of transition and the frequency of unemployment and precarious employment over various years. A further type of analysis tries to examine whether the process of transition is facilitated by certain types of prior education and training, e.g., a close 'coupling' of education and training to respective occupations, notably through the apprenticeship systems (cf Shavit and Müller, 1998), whereas others consider 'market' regulation, as observed notably in the USA, as most promising because it facilitates adjustments at any time in the career.

Various studies address factors other than educational achievement that might explain transition to employment and further career. 'Credentials,' for example, both certify and symbolically overemphasize educational achievements. Also, sociobiographic background comes into play not merely in terms of particularistic advantages in the transition processes, but also in terms of social skills not taught through formal educational processes. Further, the terms of 'key qualifications' point out the importance of competencies in part fostered by education and training. Moreover, transition from education to employment also can be viewed as a moment under reduced meritocratic rule when young people can seek for chances through diligent search, smart tactics, and the demonstration of

talents so far not rewarded in education. Finally, some analyses indicate moderate impacts of targeted measures of improving transition to employment, notably short training programs for 'at-risk youth' and occupational guidance and counseling as well as placement arrangements by public employment agencies, private recruitment, and placement firms, and by placement support on the part of educational institutions.

Concluding Observations

Education became increasingly an important determinant of employment and career in the nineteenth and twentieth centuries. By and large, long periods of vocational learning are rewarded by a higher status and more interesting and independent work. However, this is affected by labor market situations of demand and supply. Also, education becomes, in the process of expansion, more and more a prerequisite for career success, whereby other factors might gain weight with respect to the details of selection and allocation. Finally, the growing dynamics within the occupation system make the influence of vocational education less visible when lifelong education grows.

International comparison has pointed out a striking variety of modes of education and training and of links between education and employment. The debates continue on the virtue of general vs. specific education, on hopes set in educational expansion vs. a closer match between education and the demands of the economy, on the advantages of a close coupling between training and work vs. open market regulations, etc. But international comparison also questions the beliefs widespread in the 1960s that one could identify the most successful, modern way of shaping the education system in a most promising way for serving economy, culture, and personality development. This did not necessarily lead to a dominance of relativistic approaches, but rather often stimulated the search for new mixes, e.g., in combining general education with work experience, opening up avenues for tertiary education while intensifying measures for educationally disadvantaged youth, improving education and concurrently measures that address the transition processes directly as well as 'employability' in other respects.

Even in a 'knowledge society,' one does not expect that a more or less pure educational meritocracy will emerge, because other factors might increasingly gain momentum. But education seems to remain the single most important determinator of career and other life chances.

Abstract

This article discusses the relationships between income and education. The first section focuses on the effects of income on various educational outcomes and the second half discusses the relationship between education and earnings. Although the gross bivariate relationship between family income and education is moderately strong, the causal impact of income is very much weaker after taking into account other aspects of socioeconomic background and cognitive ability. Education is almost invariably the strongest influence on earnings and in the United States the returns to education, especially postsecondary education. Although other countries in the 1980s and 1990s also experienced increasing returns to education, more recent studies conclude little change or even decreasing returns to education in countries other than the United States.

Effects of Income on Education

According to the economic resources approach, economic inequality is the prime generator of differences in student performance. The essence of this approach is that parents either can or cannot afford to 'buy' educational success for their children. They can do this by sending their child to a high-fee private school or buying (or possibly renting) a house or apartment in the catchment area of a high-performing public school which tend to be located in more expensive neighborhoods. In some countries, parents commonly employ personal tutors to improve their child's performance. At the other end of the economic spectrum, poorer families cannot buy the essentials: textbooks, reading books, and other educational resources; and possibly their crowded living areas do not provide enough space for focused productive study. In reference to college education in the United States which can be very costly, the economic argument focuses on credit constraints; poorer families are unable to borrow the money necessary for a good education for their child (Becker, 1975; Carneiro and Heckman, 2002). Such credit constraint arguments do not apply as well, or not at all, in countries where university education is largely free or has relatively low upfront costs.

Overall Relationship

Family income is significantly related to student achievement and other educational outcomes. Sirin's (2005) meta-analysis of mainly small studies conducted in the United States between 1982 and 2000 found that the average effect size (adjusted correlation coefficient) for the bivariate relationship between family income and student achievement was around 0.29 comparable to effect sizes of 0.30 and 0.28 for parental education and father's occupational status. This contrasts with White's (1982, p. 470) earlier meta-analysis which found that family income ($r = 0.32$) showed stronger correlations than parental occupation ($r = 0.20$) or education ($r = 0.19$). Ganzach (2000) reports a correlation of 0.30 between household income and educational attainment in the NLSY79, although the correlations with father's or mother's education were larger (at about 0.45).

Increasing income gaps in educational outcomes in the United States have been documented by a recent edited book (Duncan and Murnane, 2011). Between 1978 and 2008, the gap in students' mathematics test scores grew by one-third. In contrast the effect of parental education is quite stable. The increase in the impact of income is accounted for by wealthier parents more heavily investing in their children's cognitive development (Reardon, 2011). Similarly, income differences in college completion increased. The proportion of young people completing college increased by 21% points between cohorts starting school in the mid-1990s compared to cohorts starting school in the mid-1970s compared to only a 4% point rise among comparable low-income cohorts (Bailey and Dynarski, 2011). For the general increase in income inequalities in educational outcomes a variety of explanations are offered such as increasing economic segregation of schools, increases in single-parent families, the lack of resources of families in poverty, and the increased time spent by wealthy families on the cognitive development of their children. However, it is not clear if the increases in the income gap can be attributed to increases in the importance of cognitive ability as argued by Herrnstein and Murray (1994). For educational attainment, Duncan et al. (2013) conclude that the gap in the completed schooling between children in the top and bottom quintiles of the family income distribution increased by about half a year between the late 1960s and late 1990s. Increases in income inequality accounted for between two-thirds to three-quarters of the increasing schooling gaps between high- and low-income children but there was no increase in the effect of family income on educational attainment. One important contributing factor was increases in maternal age which is predictive of schooling.

Net Effects

However for educational outcomes, the impact of family income, net of other socioeconomic background factors, tends to be weaker than economic explanations of socioeconomic inequalities in education would predict. In the Wisconsin Longitudinal Study, family income was obtained from state tax records and averaged over 4 years (Sewell and Hauser,

1975, p. 18). It displayed surprisingly weak correlations with test scores (0.18) and educational attainment (0.28). In a regression analysis of educational attainment the standardized effect of family income ($\beta = 0.12$) was smaller than that for father's education ($\beta = 0.22$) and father's occupational status ($\beta = 0.14$) (Sewell and Hauser, 1975, pp. 72–73). In an earlier publication Sewell and Hauser (1972, p. 856) comment, "there may be little merit in the efforts of some social scientists to interpret all social inequalities in terms of income differences." Analyzing mathematics score in the NELS88 study, Fejgin (1995, p. 24) reported a standardized effect of 0.07 for family income compared to 0.32 for parents' education. An even weaker standardized effect ($\beta = 0.05$ for family income) was found for reading achievement. Analyzing mathematics achievement score in the children of the NLSY79 study, Orr (2003, p. 291, 293 model 2) reported no effect for family income (averaged over 5 years) on mathematics achievement, net of father's occupational status, mother's education, mother's AFQT score, and other variables (not including wealth).

In Olneck's (1977, footnote 1) analysis of educational attainment using sibling data, the addition of average family income over 3 years did not increase the explained variance beyond that provided by father's and mother's education, and father's occupation. According to an early analysis of the PSID, family income averaged over 5 years had no effect on young men's educational attainment, net of a crude measure of ability and father's education (Kiker and Condon, 1981, p. 102). In a review article, Haveman and Wolfe (1995, p. 1856) conclude "changes in economic resources are associated with only small changes in educational attainment." They cite Hill and Duncan's (1987) analysis of the PSID where a 10% increase in family income (averaged over 3 years) was associated with an increase in educational attainment by only 1.4%, less when controlling for other social background factors. Similarly, Belzil and Hansen (2003, p. 694) conclude that for educational attainment, father's and mother's education have much stronger effects than family income. A 1-year increase in parental education, on average, increases years of education by 0.3 of a year. To obtain a similar increase requires a difference of $30 000 in income, a large difference given the average income for that study (conducted in 1990) was $37 000. For school completion Belley and Lochner (2007, p. 51) found only a 7 or 8% point difference in school completion rates between the top and bottom family income quartiles, net of measured AFQT quartile and mother's education.

In the United States going to college is often expensive, so income should have stronger effects for college entry than school completion. However, economic factors play a minor role compared to academic and social factors. Hearn's (1988) analysis of factors that influence the cost of the institution attended concludes that the relatively minor effects of SES and ascriptive factors are more 'social' than 'economic.' Cameron and Heckman (2001, p. 485) found that family income has an important role at explaining grades at age 15, a modest role in high school continuation decisions but 'no role in college entry decisions' and contrary to prevailing economic theory conclude that credit market constraints are not a strong determinant of college choices. Belley and Lochner (2007, pp. 51–52) found modest effects for family income in the 1979 cohort; the difference in college attendance at age 21 between the top and bottom income quartiles, net of measured ability, was 9% points. For the NLSY97, the difference had risen to 16% points. This analysis included ability quartile but the only 'social' factor included was mother's education. For enrolling in U.S graduate programs, family income has only weak effects. Net of GPA and other factors, a $10 000 increase in income increases the probability of graduate school enrollment by only 0.37% (Zhang, 2005, p. 324). Morgan and Kim (2005, p. 177) also found small effects. They conclude, "that giving the average family $6000 per year in family income would increase the college enrollment rate among their adolescents by an additional two-thirds to one full percent." (The median and mean monthly incomes were around $2500 and $3000.) However, they do not regard this effect as causal, since other home background and academic performance measures were not included.

Furthermore, family income has only weak effects on social, cognitive, and behavioral outcomes among children (Aughinbaugh and Gittleman, 2003; Blau, 1999). Mayer's (1997) analysis of the PSID and NLSY79 also concluded that the influence of family income on social and economic inequalities is, at best, modest when taking into account other family characteristics.

It is not only in the United States where the effect of income on educational outcomes is weak. Bratti (2007) finds significant negative effects for household income on dropping out of school in England and Wales, but concludes "the magnitude of the effect is relatively small" (2007, pp. 36–37). After analyzing age finished formal education using the 1958 and 1970 British Cohort studies, Chevalier and Lanot (2002, p. 1879) conclude that "the effect of family income on a child's schooling attainment is rather limited." In their regression equation, family income was often not statistically significant, especially when controlling for ability. In the United Kingdom, Blanden and Gregg (2004) identified a small effect of income in the 1970 BCS controlling for unmeasured differences between families using a fixed effect model: a decrease of one-third in household income reduced the probability of obtaining a degree by between 1% and 6%. The effect of household income may have increased when compared to the British Household panel. According to analysis of the BHPS, the comparable effect was between 3% and 7%, although the BHPS does not include comparable measures of childhood ability.

In Canada, the association between dropping out of school and family income is weak (Foley et al., 2009). The effect of family income on university participation is very weak with R square values less than 4% and in some years less than 1% (Corak et al., 2003). For New Zealand, Fergusson et al. (2008) conclude that a family's economic resources (and the socioeconomic level of the school) do not mediate the relationship between socioeconomic background and educational achievement. Much of the relationship was mediated by a child's cognitive ability (35%) measured at ages 8, 9, and 13 years followed by educational aspirations. Analyzing educational attainment in Ireland, Chevalier and Lanot (2002, p. 179) found weaker effects for family income compared to other family characteristics. For Sweden, Erikson and Jonsson (1996, pp. 21–22) conclude "background factors other than economic resources are important in explaining the association between social origins and educational decision," although they suggest

that economic resources may be important for the transition to university. For Denmark, Jæger (2007, p. 546) found no significant effects on completing secondary school for family income, home ownership, car ownership, or summer house ownership for the youngest generation and only family income mattered for the parental generation. He concludes, "economic capital has largely ceased to predict educational attainment" (2007, p. 546). In Germany, income plays a much smaller role than parental education in the allocation of students to different academic tracks (Schneider, 2004). For Poland, the impact of income on educational attainment is generally weaker than that for other aspects of socioeconomic background, such as parent's education (Beblo and Lauer, 2004). For the Netherlands, the effect of monthly income on education level was about one-third that of parental education (Vollebergh et al., 2001). Less direct evidence is provided by Vries and De Graaf (2006, p. 226), who found no effect for father's occupational status (which is indexed by each occupational group's mean income and education), and conclude that 'the economic dimension does not matter in the Dutch Education system.' This conclusion was consistent with earlier research which concluded that financial resources were important in the Dutch education system before 1950 but not since then. The change is attributed to policies which removed financial barriers to education (de Graaf, 1986). In Norway, family income had no effect on grades at university when controlling for secondary school grades (Hansen and Mastekaasa, 2006, p. 284). Japan is a possible exception to the general pattern of family income having limited effects. The impact of family income on continuing education beyond the minimum school leaving age and academic qualifications was higher in Japan than in either Britain or the United States (Ishida, 1993).

Effects of Education on Earnings

Economists approach the relationship between education and earnings as the rate of return. This perspective is consistent with human capital theory where education is understood as an investment in future earnings. The rate of return is the percentage increase in earnings for each additional year of education, sometimes minus the costs of education and foregone income while studying. A similar methodology is used for the returns to primary, secondary, and tertiary education.

The rate of return is separated into private and social rates of return, separating the benefit accruing to individuals and the benefit to society more generally. According to the OECD, the private rate of return is equal to the discount rate that equalizes the real costs of education during the period of study to the real gains from education thereafter and includes the costs equal to tuition fees, foregone earnings net of taxes adjusted for the probability of being in employment minus the resources made available to students in the form of grants and loans. (From the OECD http://stats.oecd.org/glossary/detail.asp?ID=5412.) The social rate of return includes the increased productivity from education and a host of noneconomic benefits of better health, more social cohesion, and more informed and effective citizens minus the public costs of providing education. (From the OECD http://stats.oecd.org/glossary/detail.asp?ID=5426.)

There are a variety of related issues. The rate of return is unlikely to be constant for each additional year: the year completing school or completing a degree is likely to be higher than completing other years of education. There is also variation in the returns with some types of education (e.g., medicine, business) relating to higher earnings, whereas vocational qualifications are associated with lower earnings compared to university or college education. Another issue is the extent that the private returns represent the true returns to education or are biased upward because of the ability premium; higher ability persons tend to have higher levels of educational attainment and higher incomes. The private returns to education is an important concept in studies of discrimination: the extent that gender, racial, and other group differences in earnings are due to differences in endowments or differences in the returns to endowments (Jones and Kelley, 1984).

According to Psacharopoulos (1985, 1994) and Psacharopoulos and Patrinos (2004), the private rate of return in OECD countries (per year of education) is around 7–8% and higher in less developed countries such as Sub-Sahara Africa (13%), Asia (10%), and Latin America (12%). For higher education the private rate of return in OECD countries is about 12%, but 20% for the whole world. The returns to women (10%) are higher than those for men (9%) and higher in the public sector compared to the private sector. The estimates for the social rate of return are more difficult to estimate consistently and tend to be lower around 9% for OECD countries. Both the private and social rates of return have declined.

The impact of education on income is increasing in the United States (Burbidge et al., 2002). Gottschalk and Joyce (1998, p. 496) document strong increases in the impact of a college education for earnings in the United States between 1979 and 1981 of around 1.6% per year. There was a slightly weaker increase of 1.1% between 1986 and 1991. Lemieux (2006) concludes that the bulk of the rise in wage inequality from 1973 to 2005 in the United States is accounted for by increasing returns to postsecondary education relative to secondary education increased returns to postsecondary schooling. Deschenes (2006) concluded that causal return to education increased by 20–40% between 1979 and 2002 with no change in the ability premium. In contrast, Kaymak (2009) concluded that the returns to earnings for a 1-year increase in education increased from 4.8% to 8.4% between 1964 and 2003, and argues that the increase in the education premium after 1990 was caused almost entirely by ability.

In the Gottschalk and Joyce (1998) study the countries with the next strongest increases in the returns to college education after the United States during the 1980s were Sweden and Finland, two countries that did not experience an increase in earnings inequality. There were weaker increases for Canada, the United Kingdom, the Netherlands, and Australia. More recent evidence for the United Kingdom is mixed. Silles (2007) found increased returns to education among men but not among women, whereas Walker and Zhu (2008) found no evidence of increases in the college premium. However, there is little evidence for increasing effects of education for earnings for countries other than the United States and Great Britain: Australia, Canada, Norway, and the United Kingdom

Table 1 Effects of educational attainment and other influences on earnings

Country	*Educational attainment*	*Gender*	*Parents' education*	*Language native versus other*	*Literacy score*	*Labor market experience*	*R square*

Switzerland	0.40	0.39	−0.06	0.01	0.12	0.29	0.39
United Kingdom	0.38	0.37	−0.06	0.03	0.29	0.17	0.48
United States	0.38	0.36	−0.02	−0.04	0.24	0.11	0.43

25–55 year olds. Presented are standardized regression coefficients from Structural Equation Modeling. Educational attainment is a latent variable constructed from both years of education and formal qualifications in some countries and only one of these in others. Literacy score is a latent construct based on the Prose, Document, and Quantitative Scales. Experience (in the labor force) is estimated by age minus years of education minus 5. 'Earnings' is measured on an interval scale based on quintiles since some countries did not collect or release continuous wage data.
OECD & Statistics Canada (2000, p. 175).

(Burbidge et al., 2002; Coelli and Wilkins, 2008; Haegeland et al., 1999; Marks, 2009). In Ireland and Spain, the returns to education have declined (Blázquez et al., n.d.; Voitchovsky et al., 2012). It is surprising that the returns to education have not decreased in many more industrialized countries, despite large increases in the proportion of the workforce with college degrees.

Sociological Approaches

In sociology, the theoretical background for the intergenerational income correlation is more an extension of the socioeconomic inequalities in educational and occupational attainment. The status attainment approach understands earnings, income, and wealth distal in a sequence of causal pathways. Earnings are understood as a dependent on occupation: in the "context of the allocation of occupational roles and related prerequisites" (Sewell and Hauser, 1975, p. 3). In other words, earnings depend on jobs. The causal sequence begins parents' characteristics, usually parental education and occupation, but can include family income and more rarely family wealth. These factors influence educational attainment mediated by mental ability, grades at school, aspirations, and expectations. In turn educational attainment influences income both directly and via occupation. Although father's earnings or family income is part of the causal sequence since parents can purchase schooling or other desirable goods for their children, economic background is given no special prominence in the causal pathway. The major focus is on the social forces that shape education and occupational attainment and, as a consequence, earnings.

A meta-analysis of the impact of cognitive ability and education on earnings estimated a standardized coefficient of 0.22 for education and 0.15 for ability (Bowles et al., 2001, p. 1154). Analysis of earnings in the 1992 U.S Adult Literacy Study produced standardized effects of 0.29 for educational attainment for white men and 0.31 for white women (Kerckhoff et al., 2001, p. 17).

According to the 1994–98 International Adult Literacy study, there are substantial effects of educational attainment on income net of gender, parent's education, literacy, and employment experience across industrialized nations. **Table 1** presents the standardized effects. The effects of educational attainment are substantial in every country with standardized coefficients between 0.17 and 0.46.

Abstract

A life span perspective on education gives consideration to the way in which education early in the life span alters trajectories of development throughout the life course, as well as to the ongoing effects of continued engagement in lifelong learning on development. Given the fact of longer life spans for successive generations, the ever-accelerating pace of knowledge development needed for work and managing everyday affairs, and the contributions of education to optimizing developmental outcomes, it is important that new models of life span education are developed.

Traditional assumptions hold that education and learning are primarily early life span endeavors that serve to prepare individuals for occupations and civic engagement. Such a limited view of the role of education is being overturned by a relatively recent shift in the understanding of the nature of adulthood and aging. Rather, lifelong education is essential for the healthy development of both individuals and societies.

First, there is accumulating evidence that the education of both formal and informal sorts contributes to lifelong health, well-being, and cognitive resilience. Further, the capacity to take the advantage of education and opportunities for learning is present throughout adulthood into very late life. Thus, access to education throughout the life span is an important facet of sound public health policy.

Second, driven in part by advances in medicine, we are living longer. Population aging on a global scale is unprecedented, pervasive, and projected to endure (United Nations Department of Economic and Social Affairs Population Division, 2002) so that by 2050, for the first time in history, the proportion of adults over the age of 60 is expected to match the number of people who are younger than 15 years of age. With this shift, conventional models of education, in which individuals are educated early in the life span to prepare for work and civic responsibility in adulthood, are no longer tenable. Such models were predicated on the assumption of shorter expected life spans relative to today. Longer lives are leading to trends for a more extended time engaged in work, even while the nature of work and the knowledge and skills required for work, are changing at an ever-accelerating pace. The consequence is that it is simply not feasible to educate children and young adults for the jobs they will have 40, 50, or 60 years hence. Also with this shift, conventional models of retirement, in which large numbers of younger people in the workforce support an extended period of disablement and/or leisure for a relatively small population of older adults, are no longer economically feasible. Some time ago, Riley and Riley (2000) identified these problems as ones of 'structural lag', in which the social structures that defined the roles available to individuals at particular ages were lagging behind the profound changes engendered by longer life spans. The upshot is that these age-segregated social structures must be transformed, so that education is accessible throughout the life span if we are to optimize health, well-being, and human capital.

Finally, a substantial number of individuals, for a variety of reasons, do not fully acquire literacy, numeracy, reasoning, and other basic skills needed for full participation in adult life during early life span educational experiences (National Research Council, 2012). Such individuals find their way to adult basic education programs, disability services in universities, and work-related training programs, often with some urgency of educational need, but with complicated adult lives. For such people, education science must offer efficient and effective means of meeting educational goals within the constraints of a busy adult life.

Thus, education is very much a life span enterprise. We open our review by considering the nature of life span cognitive development. Then we discuss the effects of education on development – first from the perspective of what early life span education contributes to lifelong development, and then from the perspective of how adult development and aging may be shaped by ongoing educational activities. Finally, we return to the issue of structural lag by considering new models of life span education.

Life Span Cognitive Development

Life span psychology is now a mature area of inquiry (Baltes et al., 1999), and it is widely recognized that development is incomplete at the transition into adulthood and extends across the entire life span. An understanding of the core tenets of life span psychology provides important grounding for conceptualizing the role of lifelong education.

Development Is Both Holistic and Multifunctional

An important contribution of life span psychology is a melding of both person-centered (holistic) and function-centered approaches. Development is multifunctional in the sense that the system comprises processes (e.g., perception, memory, reasoning, regulatory mechanisms, identity, dispositions, social strategies) that define the way in which the individual (at the system level) experiences the world and is able to adapt to it. Nevertheless, development is holistic in the sense that the person, with a unique constellation of these functions (e.g., abilities, dispositions, values), develops as

a system such that there is coherence across developmental periods or stages.

Development Is Multidirectional

Component processes constitute distinct functions that can interact but develop independently as a function of biological, environmental, and cultural resources. The consequence is that development is necessarily multidirectional. Development can be multidirectional in the sense that functional systems show divergent trajectories from one another. For example, sensory and perceptual systems generally show declines with age as a consequence of the biological process of aging, while the capacity for knowledge growth, which thrives on environmental enrichment and cultural context, appears to be fairly well preserved into very late life. Development can also be multidirectional in the sense that processes within functional systems can show divergent trajectories. For example, consider the case of problem solving: biological constraints may place limits on certain facets of cognition involving speeded processing of novel patterns with age, leading to declines in inductive reasoning, while life experience may afford growth in reflective judgment, contributing to expertise in social problem solving.

Among the most salient examples of multidirectionality in adult cognition is the divergent development of fluid and crystallized abilities. Fluid abilities or 'mental mechanics', the ability to apprehend and mentally transform novel patterns, are highly vulnerable to age-related biological declines, whereas crystallized abilities, which rest on knowledge and well-learned skills, are relatively resilient. Another example of multidimensional development is in the motivation for learning, which may be driven primarily by the need for information acquisition early in the life span, but by social–emotional concerns later in the life span.

Plasticity Is Present Throughout the Life Span

Plasticity, the capacity for change in response to experience, exists throughout the life span. Plasticity is distinct from flexibility, defined by one's current skill set that enables adaptation within a particular range of demands, and implies the ability to both gain in efficiency and form new representations (Lövdén et al., 2010). Thus, plasticity implies the capacity to increase in flexibility. So, for example, learning a second language is likely to increase the range of situations in which one can function, that is, flexibility, and depends upon existing plasticity. Some evidence suggests that bi- or multilingualism enhances cognitive function more broadly (e.g., cognitive control, ability to learn vocabulary in a novel language; Bialystok et al., 2010); to the extent that this is the case, it would suggest that learning a second language may enhance plasticity itself (i.e., enhancing potential for learning in new domains). Some theorists argue that the hallmark of plasticity at the neural level is structural alteration in networks, while changes in activation within existing neural networks define flexibility (cf Lövdén et al., 2010). By this view, plasticity is a sluggish capacity, which can be thought of as adaptive, since a system that was incessantly rewiring itself would be unstable and ultimately maladaptive. As an adaptive capacity to respond to new demands, plasticity requires a relatively long-term mismatch between demands and existing skill sets. Importantly, current levels of flexibility contribute to the range of environmental presses to which the individual can respond with increased plasticity: demands that do not challenge current skill sets do not engender plasticity, nor do demands outside the range of current skill sets afford a fruitful engagement with the experience. This notion that development and learning depend on experiences that challenge the system within an optimal range is pervasive in the psychological literature, at least since Vygotsky's discussion of the *zone of proximal development*, and more recently, in Metcalfe's work on the *region of proximal learning* (e.g., Metcalfe and Kornell, 2005).

While plasticity is at the core of human nature, there is wide individual variation in plasticity, so that some individuals require a more prolonged experience of increased demand to increase adaptive capacity. As a rule, plasticity tends to decrease later in the life span, as a consequence of age-related limits on neurogenesis, so that plasticity may become increasingly sluggish. At the same time, individual variation in plasticity is certainly present throughout the life span.

Implications for Education

Education and life span developments are intimately related. On the one hand, it is important that we understand how education contributes to development. On the other hand, we must know how to create instructional programs that can effectively teach individuals at different stages of the life span. One consequence of multidimensionality and plasticity is that adults become increasingly different from one another, so that a life span perspective on education implies developing instructional approaches that can accommodate such variation. In the next sections, we review what is known about the lifelong effects of education early in the life span, and then consider how education can shape development during adulthood.

The Effects of Early Education on Life Span Development

Educational experience during youth and young adulthood can confer a number of lifelong advantages. Perhaps obviously, this can include skills and regulatory capacities that contribute to employment and social mobility, and dispositional attributes that engender plasticity by enabling comfort with novelty, or sustained investment in stimulating activities. Perhaps less obvious, but the focus of much recent research is that education can have lasting effects on brain and cognitive health into late adulthood.

It has long been recognized that educational level, psychometric intelligence, and socioeconomic status (SES) or income are correlated. These interrelationships are likely multidetermined and complex. Because intelligence tends to be a moderately reliable individual difference throughout the life span, and because individuals are selected into educational experiences based on demonstrated intellectual merit, the effects of education on intelligence are difficult to parse out. However, there are good reasons to believe that at least some of

these effects can be directly attributed to the effect of education on intellectual development. For example, based on evidence from 'natural experiments' (e.g., accidents of geography or history that impact educational opportunities largely without regard for talent), Ceci and Williams (1997) concluded that education is a direct cause of intellectual growth. This is not an uncontroversial position given arguments that intelligence is relatively immutable and that education primarily serves the function of selection among those with intellectual capacity, rather than playing a direct role in intellectual growth (Herrnstein and Murray, 1994). Nevertheless, there is increasing evidence for the plasticity of intelligence and the important role that education plays in this plasticity. A recent example of a natural experiment of the sort described by Ceci and Williams comes from Brinch and Galloway (2012), who examined the effects of school reform in Norway on increasing the level of compulsory education, and subsequently increasing IQ scores in adolescence.

The availability of large-scale longitudinal data sets that include measures of childhood or young adult intellectual function, educational attainment, and occupational and health data (e.g., Scottish Mental Survey, Lothian and British Cohort Studies, Project Talent) has spawned a new area of inquiry over the last decade, called 'cognitive epidemiology', which examines the longitudinal correlates of intelligence early in the life span. A strikingly well-replicated finding is the ability of intelligence to predict health in adulthood, as well as mortality (Deary, 2012), a topic to which we will return in a moment. Another consequence of such large longitudinal data sets is the opportunity to use sophisticated statistical techniques to examine mechanisms underlying differential development using mediational models (cf MacKinnon et al., 2007). So for example, evidence from the British Cohort Study (cf Deary, 2012) suggests that the relationship between childhood IQ and SES is mediated by educational investment. Of course, questions about the impact of educational engagement on intellectual growth, health, and SES inevitably depend on correlational data, and even with the most carefully done structural equation modeling, the best we can do is test whether the data are consistent with causal accounts, so that debate on this issue is lively (e.g., Deary and Johnson, 2010, 2011; Richards and Sacker, 2011).

The rise in intelligence test scores for successive generations (Schaie and Zanjani, 2006) is likely attributable to a number of factors, including conditions that promote better health (e.g., sanitation, medical advances), but also better access to education for later cohorts. The plausibility of the conclusion that education serves a distinctive role in this cohort drift in intelligence is strengthened by examining divergence in particular abilities: while primary mental ability scores on verbal meaning and inductive reasoning have shown robust increases across cohort, numerical skills have tended to decrease, declines that coincide historically with the advent of calculators.

A recent study by Ritchie et al. (2013) used longitudinal data from the Lothian Birth Cohort (LBC) 1921 and 1936 studies to examine the education–intelligence link. On 1 June 1932, the Scottish Council for Research in Education administered an assessment of general intelligence to every 11-year-old child in the country who was in school that day, with the goal to get data on the distribution of intellectual capacities across Scotland. As a result, about 95% of the population of 11-year-olds was tested – at a point prior to the onset of ability-differentiated education. In an effort to understand possible generation differences in intelligence as a result of historical change in family structure, the Scottish Council repeated this effort in 1947. The LBC studies are follow-up assessments of those living the Lothian region of Scotland in old age. Ritchie et al. (2013) took advantage of this extraordinary data set to address the question of whether education contributed unique variance to intellectual capacities in late life. Controlling for intelligence at age 11 and SES, the researchers found that educational level was predictive of intelligence scores in late life. Interestingly, the advantages of education were greater for those with initially lower intelligence test scores. Additionally, there were no reliable effects of education on speed of processing tasks, an indicator of low-level cognitive processing. Collectively, this research strongly points to education in youth as an important contributor to intelligence. Given the relatively strong predictive relationship of intelligence to many life outcomes (Deary, 2012; Kuncel et al., 2004), it may be that these outcomes can be in part attributed to education.

Perhaps among the most startling findings from cognitive epidemiology is the discovery that educational achievement early in life is predictive of health, mortality, and cognitive resilience in old age. As with the education–intelligence link, it is challenging to isolate causal mechanisms. For example, it is plausible that education could promote health by conferring economic advantage that enables better access to medical care; by shaping dispositional traits, like conscientiousness, that engender skills in self-regulation and self-care that promote health by establishing a lifestyle early in the life span that engenders habits of mental stimulation that promote intellectual growth; and/or by establishing a consistent and predictable environment that buffers against the toxic effect of stress. It is also plausible that a life course of generalized fitness is created early in the life span by some combination of genes, prenatal, and early life experience that predisposes individuals to both take advantage of education and experience good health. Of considerable interest in the current research, literature is the proposal that early educational experiences directly offset normative and pathological effects of aging to engender cognitive health.

The constructs of 'resilience' and 'reserve' have appeared in the aging and adult development literature to broadly capture the ideas that older individuals may be able to avoid pathological risks associated with aging, and normative age-related cognitive declines, respectively. A well-replicated finding in clinical neuropsychology is that there is often a disjunction between the degree of brain pathology and the clinical manifestation of such pathology on behavior (e.g., cognitive performance or the ability to manage everyday activities). In particular, at autopsy the brains of relatively well-educated individuals often show *more* evidence of brain pathology than those of less well-educated individuals, who had comparable levels of cognitive function prior to death. 'Reserve capacity', the idea that education engenders neural and cognitive growth that buffers against the assaults of pathology, has been used to explain such findings

(Christensen et al., 2008; Stern, 2009). It is certainly well established from both animal and human training models that experience can induce neurogenesis (i.e., the growth of neural networks) (Draganski et al., 2004, 2006; Kramer et al., 2004).

Some researchers have distinguished between passive and active models of reserve. Passive models of reserve emphasize the neuroprotective effects of variation in the capacity of the brain to withstand pathology. Measures of interest in such passive brain reserve models include head circumference, brain volume, synaptic density, or other biophysical attributes. Once a threshold is reached, both normative effects of aging (e.g., changes in hippocampal volume) and pathological effects of aging (e.g., amyloid plaques and neurofibrillary tangles) manifest themselves clinically and behaviorally. This model assumes that, holding all other things equal, neural networks that are larger or more robust are capable of withstanding more damage before the damage manifests itself functionally. So, for example, there is evidence that education buffers against normative declines in volume of the hippocampus, a brain structure critically involved in encoding new memories (Noble et al., 2012). By contrast, active models of reserve emphasize the degree to which individual differences in task processing (e.g., alternative cognitive strategies, differential recruitment of networks) contribute to cognitive optimization, which can allow some people to cope better than others with "brain changes in general and aging in particular" (Stern, 2009: p. 2027). Such models posit that individuals with greater cognitive reserve are able to compensate for the effects of aging through compensatory changes in neural recruitment (such as increased recruitment of contralateral hemispheric homologues), or through the use of different cognitive strategies (such as an increased reliance on prior knowledge). So, for example, Ritchie et al. speculated that the effects of education on intelligence test scores but not on tasks of processing speed (as described above) may be due to the greater effects of education on active reserve. Note that explanations in terms of active and passive reserve are not mutually exclusive, as compensatory cognitive strategies result in changes in neural recruitment.

Studies that have examined the dual influence of both early education and more proximal variables have found evidence to support the notion that early educational level provides unique predictive validity for later cognitive health. Researchers have found both independent and synergistic effects of education with other potential covariates, including health status, late-life cognitive activities, and premorbid intelligence. Some studies have shown independent contributions from education, while others have shown larger effects of later life health and lifestyles choices on cognition among those with lower levels of early formal education. This suggests that early educational experiences may buffer against the influence of later life choices on cognitive health.

Although early life span educational attainment shares a high correlation with later life cognitive ability, it is unclear if the influence of education on rates of dementia is due to an attenuation of declines in cognition among the more highly educated. Some studies have found evidence that education moderates the rates of cognitive decline, but recent results from the Atherosclerosis Risk in Communities Study, a large-scale ($N > 9000$) study of community-based, ethnically diverse elders, report no effects of education on age-related declines in episodic memory or verbal fluency over 15 years, despite high correlations between education and initial cognitive abilities (Schneider et al., 2012). While findings from such large samples cast doubt on the prospect that early educational attainment slows cognitive decline, such findings should be interpreted carefully.

One issue clouding the interpretation of the effects of education on cognitive change is the use of total number of years of education as a proxy for educational attainment and cognitive reserve. Self-reports of the total number of years educated have proven to be surprisingly strong indicators of cognitive reserve (Stern, 2009). At the same time, more proximal measures of cognitive reserve capacity and educational attainment may exist, especially in populations for which number of years of education may not adequately capture the quality of educational opportunities and experiences. Indeed, measures of literacy, premorbid verbal ability, and reading comprehension have been argued to be stronger markers for cognitive reserve than the total number of years of education completed because they are more direct measures of attainment, especially among underserved populations. For example, in an ethnically diverse sample of nondemented elders, Manly et al. (2005) found that increased rates of literacy were not only associated with cognitive capacity at baseline measurement (as is commonly found), but also with slower longitudinal declines in episodic memory, executive functioning, and fluency over 8 years. Recent work has also shown that such measures of literacy are predictive of language comprehension and memory among older adults, with greater benefits of literacy for sentence recall, especially among older adults with lower cognitive capacity (Payne et al., 2012; Kavé et al., 2012).

Moreover, such longitudinal findings are difficult to interpret because the effects of education on declines in cognition likely vary quite substantially across individuals and are nonlinear in nature. Indeed, the protective effects of education appear to decrease as pathology increases in the brain, leading to the finding that highly educated individuals eventually show steeper declines in function, once a threshold of pathology has been reached (Stern, 2009). This finding, while initially counterintuitive, is central to the understanding of the effects of education on cognitive health; early life span protective factors, such as education compress cognitive morbidity, such that abilities are preserved (or effects of disease are delayed) until some time later in the life span. Indeed, some studies have estimated of the protective effects of education (comparing individuals with less than high school education versus those with more than high school education) to be equivalent of upward of 20 years of normative cognitive aging (Schneider et al., 2012). However, once highly educated adults have eventually met such a threshold of pathological burden, terminal declines in cognition begin with an accelerated negative trajectory. Due to this nonlinear trajectory that is dependent upon an individual's time relative to terminal decline, it becomes difficult to interpret the effects of education on longitudinal change without information about terminal thresholds for each individual. In studies that have examined the rates of cognitive decline relative to such thresholds, such as the onset of dementia diagnoses for example,

such education-dependent compression effects have been observed (see Stern, 2009).

Lastly, it has been argued that 'full' tests of the effects of education on cognitive and brain reserve are lacking in the literature, as a test of the model requires a measure of reserve (e.g., education, occupational, or activity engagement), a measure of neural integrity or pathology (e.g., brain amyloid), and a measure of cognitive ability or clinical impairment (Christensen et al., 2008). Findings from the religious orders study (Bennett et al., 2003) provide a particularly clear example of a 'full' test of cognitive reserve among the highly educated. This study found that higher levels of dementia-related brain pathology (e.g., amyloid plaques, neurofibrillary tangles, Lewy bodies) at autopsy were associated with lower levels of cognitive function before death. However, the correlation between markers of brain pathology and measures of cognitive function was attenuated among those with higher levels of formal education. Other recent results, such as those from the Epidemiological Clinicopathological Studies in Europe (EClipSE) collaboration (EClipSE Collaborative Members, 2010), support active models of the compensatory effects of education on dementia precedence in older adulthood. EClipSE included harmonized longitudinal data from three population-based studies that each included postmortem brain donation, clinical investigation of dementia, and measures of educational attainment ($N = 872$). Interestingly, while education was associated with decreased dementia risk and overall greater brain size, there was no relationship between education and risk of neurodegenerative disease or vascular pathology. However, education did moderate the degree to which all measures of neurovascular pathology were associated with the clinical expression of dementia. These results suggest that even though higher education does not provide direct protection against vascular and neurodegenerative disease (but may indirectly, through the association between education and overall brain size), higher education does buffer against the negative effects of neuropathological burden on cognitive function.

Education in Adulthood

Education in adulthood in formal settings (e.g., courses with defined goals, criteria for success, and evaluation) is not currently normative. However, such formal educational experiences have the potential to contribute to adult development along a number of lines, including the enhancement of work-related skills, acquisition of knowledge and skills to effectively manage everyday life (e.g., parenting, managing health care for a family, retirement decisions), and as a pathway to lifelong health. Currently, educational activities in adulthood are more typically the informal sort, including investment in work, literacy activities, hobbies, and social activities.

It is surprising to many to learn that many people enter adulthood lacking in the basic literacy and numeracy skills needed to fully participate in work, family, and civic life. A recent report from the National Research Council (2012) summarized evidence, based on a nationally representative sample in the US, that only about 57% of adults have prose literacy skills that would be considered above basic proficiency, and that only about 55% have quantitative literacy skills in that range. Thus, there are many adults, who have acquired basic skills in word decoding, reading simple sentences, and arithmetic, but are unable to use these skills to draw inferences, reason, or make decisions. Thus, many of the institutions for adult education exist to provide remedial instruction to help adults develop proficiency in reading and quantitative reasoning. Adults also find their way into educational venues for work-related training, as well as instruction to support avocation-related interests.

In contrast to the literature on the lifelong effects of early education on intellectual growth, the research base on the ongoing effects of continued schooling is, perhaps not surprisingly, thinner. After all, it is not normative for adults to be engaged in formal educational activities, and when they are, they have made the choice to engage in these activities, so that cross-sectional comparisons are vulnerable to selectivity biases. Nevertheless, what literature there is strongly points to the conclusion that both formal schooling and certain forms of activity engagement can support preservation and growth in both crystallized and fluid abilities. For example, Beier and Ackerman (2005) provided a life span sample (age 19–68) of individuals with educational modules in health- and technology-related topics, and showed that existing initial strengths in fluid and crystallized abilities and prior knowledge contributed to the development of domain-specific knowledge. Hatch et al. (2007) showed that participation in work-related and elective educational experiences by the age of 43 contributed to the levels of verbal ability and verbal memory in later life when early life education, social mobility, and prior cognitive ability were controlled (thus, reducing the impact of reverse causation).

There is abundant evidence from the literature that adults can benefit from explicit training in particular cognitive abilities (e.g., speed, reasoning, memory training), though less clear are the principles by which training particular cognitive skills transfers, or generalizes to, broader cognitive capacities and knowledge growth (Stine-Morrow and Basak, 2011). Another area of relevant research is that on the effects of cognitive enrichment in the form of late-life activity engagement. Hertzog et al. (2008) extensively reviewed the literature and identified seven large-scale studies that measured both rates of activity engagement and rates of cognitive decline over time. They found significant associations across all but one of the studies, some of which had sample sizes of over 4000 individuals. Similar associations have also been found between rates of mentally stimulating activities and the incidence of cognitive impairment (Alzheimer's and mild cognitive impairment). While these findings are highly suggestive, they do not necessarily indicate a causal relationship between stimulating activity engagement and improved cognition. Muddying this causal relationship is the substantial difficulty with measuring intellectually stimulating activity, especially as perceptions of cognitive demand in an activity differ across individuals (Payne et al., 2011). Moreover, the level of cognitive activity could be a marker for other more proximal causes. Reduced cognitive activity could index early neuropathology, essentially suggesting a reversed causal direction of the relationship. Consistent with this argument is a recent longitudinal study suggesting that there

are reciprocal relationships between change in activity engagement and change in cognition, such that individuals who decline more in some cognitive abilities (e.g., speed) show later declines in activity engagement. Cognitive activity does have a more long-term influence on cognitive change over decades; however, weakening the argument that reduced cognitive activity could be solely an indicator of a prodromal period of disease-related neuropathology. Another argument that has been proposed is that cognitive activity engagement may be a marker for a number of other beneficial health and SES outcomes, which benefit the quality of life. Importantly, however, some studies have shown that the relationship between late-life cognitive activity and the incidence of Alzheimer's disease remain even after controlling for estimates of early-life cognitive activity and SES.

While engagement in formal education is not normative in adulthood, adults often do continue to work in substantively complex environments into late life, and this provides an important pathway to examine the relationship between informal educational opportunities and mental stimulation. In an interesting approach to examine the impact of work on cognitive resilience, Rohwedder and Willis (2010) compared cognitive scores across countries as a function of retirement policies, thus circumventing the issue of individual selection into complex environments, assuming that individuals have minimal control over national retirement policies. Rohwedder and Willis analyzed data from three cross-national surveys that provide comparable assessments of cognition: the Health and Retirement Survey in the United States; the English Longitudinal Study of Aging; and the Survey of Health, Ageing and Retirement in Europe, which collected data from 11 European countries. In each case, surveys were based on large nationally representative samples administered over the phone, in which cognition was assessed by delayed recall for 10 concrete nouns (a task that typically shows age declines). Results showed that individuals in countries that had policies incentivizing early retirement (e.g., by taxing earned income at a higher rate) had steeper declines in memory between the early 1950s and early 1960s, relative to those who lived in countries whose tax policies encouraged continued work. Although correlational, the relationship between engagement in work and mental decline reported by Rohwedder and Willis strongly implies that the mental demands of work promote cognitive resilience.

Conclusions: Innovating Life Span Models of Education

Based on our review, we believe that it is clear that individuals can benefit along a number of dimensions from educational experiences throughout the life span, but that a coherent model of true life span education is substantially lacking at our current point in history. In what follows, we suggest some challenges that will need to be overcome in order to meet this need. Lastly, we review some innovative models of cognitive activity engagement in adulthood that provide helpful points of guidance for future models of life span education.

The literature on the effectiveness of adult education and learning interventions is scant. At the same time, research on 'nontraditional' cognitive interventions and community-based activity engagement programs in adulthood is emerging (Hartman-Stein and LaRue, 2011), based on a substantial amount of both cross-sectional and longitudinal evidence suggesting a relationship between intellectual activity engagement and cognitive health. These intervention studies have been designed with the goal of assessing the causal effect of activity engagement on cognitive outcomes. Of these, projects that have required participants to adjust their day-to-day routines, requiring substantial time and effort commitments, appear to produce considerable benefits. One such program is the Experience Corps Project, in which older adults work as volunteers in underserved Baltimore elementary schools, working with children in literacy development activities in library settings, for example. Early findings suggested that the intervention promoted increased rates of cognitive and physical activities, as well as increases in executive control. Similarly, in the Senior Odyssey Project, older adults work in teams on creative problem-solving activities, such as building balsa wood structures that can hold large amounts of weight, and staging performances. The intervention produced positive effects on certain aspects of fluid ability (e.g., ideational fluency). Another example of a recent innovation in adult education is the Osher Lifelong Learning Institute (OLLI). There are over 100 OLLI programs associated with college campuses around the US, open to adults of age 50 and over. OLLI programs are governed by members, who organize course offerings and recruit instructors each term. Collectively, these studies have suggested that engagement in substantively complex environments may support cognitive resilience.

An optimal model of adult life span education will need to take into account normative age-related changes (and variability in changes), including declines in fluid 'mental mechanics' (e.g., executive functions, speed of processing, reasoning, episodic memory), increased reliance on cognitive strengths (such as vocabulary and general knowledge), and shifts in strategies used to solve complex problems. An important challenge to meeting this need is that adults have complex lives with competing demands, so that educational resources must be readily available and programs must be efficient in meeting learning goals. It is likely that technology will have to play some role in meeting these demands. With much public discussion over the last decades about the 'graying of America', the conversation has focused largely on adaptations needed in systems for delivering health care. Neglected is the need for equally fundamental changes in the nature of education.

Education: Anthropological Aspects

Roger Goodman, University of Oxford, Oxford, UK

Abstract

The discipline of anthropology has brought a number of important points to bear on the study of education – a relativistic perspective, a holistic approach, and the ethnographic method. At the same time, the study of education has become increasingly common in anthropological accounts, generally under the headings of the study of ethnicity and nationalism, or cognitive and psychological anthropology. This article examines the development of the anthropological study of education and explores why, despite its apparent importance, it is still looking to establish a secure niche as a subfield of the discipline of anthropology.

The study of education would appear prima facie to be central to the anthropological project, and courses that cover anthropological aspects of education are taught in a number of universities, particularly in the United States. Educational anthropology, however, has yet to create as secure a niche for itself as a separate academic discipline as, for example, medical or legal anthropology, which has become increasingly influential in the study of industrial, as well as preindustrial, societies. One reason for the lack of a clearly defined anthropology of education has been that its areas of interest and methodological approaches have overlapped so much with those of other disciplines, in particular social psychology, sociology, and, of course, the growing field of educational studies. Indeed, some of the most influential work in the study of education has been produced either in collaborative projects between anthropologists and those from other disciplines or by the latter bringing anthropological insights to bear in their own work. The influence of anthropology – in terms of scope, theory, and methodology – on the study of education, therefore, is rather more than it may at first appear.

Scope of Study

For anthropologists, the study of education is far from confined to the examination of formal educational institutions such as schools or to the experiences of those who have not yet been defined as adults. Education, in an anthropological sense, includes the whole range of learning experiences of individuals from conception to death. Indeed, to avoid the narrower connotations of the word 'education,' anthropologists have tended to use much broader terms such as 'socialization' and (less often) 'enculturation,' both of which emphasize that an individual's knowledge of what it means to be a social being is constantly refined throughout their life. The underlying assumption in the anthropological project is that every society or subsociety has an idea of what constitutes an 'educated person' (Levinson et al., 1996), but that this concept differs between societies and changes over time. One classic distinction in the study of education that many anthropologists have made is between verbal and nonverbal forms of teaching (Lave and Wenger, 1991; Singleton, 1999). The former generally takes place in formal settings, such as schools, and the latter in informal settings, such as apprenticeships. In verbal forms of teaching, the responsibility for ensuring correct understanding lies with the teacher, while in nonverbal forms it lies with the student who learns through close observation of the teacher.

In order to study such broad concepts as 'socialization' and 'enculturation,' anthropologists need to look at many features of the particular society they are examining, from kinship and religion to political and economic systems. When anthropologists study formal educational institutions – such as schools, companies, military, religious, and sporting organizations – they also take a holistic approach. They examine how these institutions reflect wider social values and attempt to inculcate them into students through formal and informal means. For example, culturally specific ideas about children and childhood in a society impinge on the educational environment in that society and lead to very different types of classroom experiences. At the same time, classroom activity in any society is presented as a 'natural' process, even though it is clearly historically and culturally contingent.

These characteristics of the anthropology of education can be understood more easily if we look at how they have developed historically and at some of their underlying theoretical and methodological assumptions.

Anthropology and Education: A Historical Overview

A history of the development of the anthropological study of education might be divided into four main periods. Ethnographers at the end of the nineteenth and early twentieth centuries generally included, in their accounts of the life-cycle of the peoples they studied, some description of how children were cared for, educated, and made full members of society, often through complex initiation rites. In many ways, these accounts differed little from those provided by travelers, missionaries, and social commentators over the previous centuries who documented their observations of the treatment of the young in the societies they visited or in their own societies. Indeed, some comparative educationalists trace their subject back to Herodotus and Xenophon in Ancient Greece and Cicero in Ancient Rome (Trethewey, 1976). Only occasionally would the earliest Victorian anthropological theorists, such as Edward Tylor,

draw on examples of educational practices from around the world in order to support their theories about how societies evolved from 'savagery' to 'civilization,' but this was never done in a systematic manner.

The beginning of what we now know as the anthropology of education and socialization, therefore, should perhaps most usefully be linked to the first attempts to theorize systematically about the socialization methods of different societies. In this project, Arnold Van Gennep, Franz Boas, and Bronislaw Malinowski were perhaps particularly important.

Van Gennep's work on rites of passage introduced the idea that, while the rituals that mark the transition between life-cycle stages within any society are often both arbitrary and flexible, the underlying pattern of ritual performance often shows a remarkable similarity across societies. At the same time, Boas in the United States, and Malinowski in the United Kingdom were among the first to challenge Victorian theories of social evolution, which equated the poor performance of certain groups in formal Western educational institutions with cultural or biological inferiority. They did this in part by showing how socialization practices are designed to meet the particular 'needs' of a society at a given point in time. Their ideas of cultural relativity that intelligence can only be judged in the context of a particular culture and not on a universal scale helped form the basis of a counterargument to the use of universal tests of intelligence in a debate that continues to rage vigorously today.

In Britain, students of Malinowski such as Raymond Firth, Phyllis Kaberry, and Audrey Richards continued into the 1930s to include in their ethnographies detailed descriptions of how children became full members of society. Followers of the alternative structural-functionalist tradition of A.R. Radcliffe-Brown, however, steered away from the study of education; they considered it to be too close to psychology and the concept of 'culture' that they eschewed in favor of the study of 'society.'

The second major phase of the development of the anthropology of education was the establishment of the Culture and Personality School in the 1930s and 1940s, the best-known proponents of which were students of Boas, such as Edward Sapir, Ruth Benedict, and Margaret Mead. This school, which enjoyed by far its greatest influence in the United States, primarily involved the application of psychoanalytic principles to ethnographic material. It proposed, among other things, that by studying child-rearing practices such as feeding, weaning, and toilet training, it was possible to understand the basis on which personality types were developed in different societies. The school is probably best known for the work of Margaret Mead; her argument that sex roles were determined culturally, as opposed to biologically, played an important part in the reexamination of cultural assumptions about men and women in many industrial societies.

The Culture and Personality School probably hit its height of influence in the wartime period with the publication of, so-called, National Character Studies, such as Benedict's classic account of Japanese society, *The Chrysanthemum and the Sword*. In the postwar period, however, such approaches became increasingly criticized for exaggerating the homogeneity of personality types within any one society and the link between early child-rearing practices and later adult behavior, for ignoring the significance of relationships that exists between societies, and for reifying society rather than regarding it as a social construction. The influence of the Culture and Personality School could continue to be seen, however, in the way data on socialization practices were collected in the Human Relations Area Files, and in the more quantitative studies of child-rearing carried out cross-culturally by Whiting and Child in the *Six Cultures Series* (1966). It was visible in the work of George and Louise Spindler (Spindler, 2000) who became probably the most influential proponents of educational anthropology in the United States in the 1960s and 1970s. It also provided an important intellectual basis for what later became known as psychological anthropology and cognitive anthropology. The culture and personality approach, however, seemed to its critics to provide little insight into the politically and historically contingent nature of socialization and educational practices and it, therefore, had little influence in British social anthropology where the study of children and education virtually disappeared from the work of anthropologists for 20 years (Richards, 1970).

What might be seen as the third phase in the development of the anthropology of education began in the late 1960s. This phase was linked, to some extent, with the growth of civil rights movements in North America and Western Europe. In the United States, it focused in particular on what anthropologists generally termed 'cultural discontinuities' in the educational experience of minority and immigrant groups within the US educational system. Detailed ethnographic studies that examined how children, who did not come from the mainstream, white, middle-class society, experienced education in the United States were drawn on to develop programs of multicultural education and greater sensitivity to the educational needs of children from different ethnic backgrounds. As John Ogbu (1981) pointed out, however, these new programs could sometimes be at the expense of essentializing – freezing in time – and stereotyping the 'culture' of minority groups.

In Britain, similarly detailed ethnographic studies were being undertaken on British schools but with the focus on issues of class rather than ethnicity. Several of these (Hargreaves, 1967; Lacey, 1971) were undertaken by members of the social anthropology department at Manchester University whose head at the time, Max Gluckman, was keen to see anthropological methods used in the study of industrial societies. Manchester today remains one of the few British universities with a course in, and undertaking research on, the anthropology of education and learning (Evans, 2006). Probably the most influential work in the UK in this period, however, was Paul Willis' (1977) study of working-class culture in a British secondary school. Willis described himself as a sociologist and he was one of the key founders of the Birmingham Cultural Studies School that drew on the neo-Marxist ideas of Gramsci. In terms of his approach, he relied on the ethnographic method following a tradition in sociology that can be traced back to the Chicago School of the 1920s and 1930s and which continues today in the field of educational studies (Walford, 2008).

The research that probably had the most lasting influence on the field of educational anthropology from the 1970s, though, was carried out by the French scholar, Pierre Bourdieu

who developed the concepts of 'cultural capital' (which the elite in society pass on to their offspring), 'symbolic violence' (which schools impose on nonelite students so that they learn to silence themselves when in the company of those with greater social standing), and '*habitus*' (the system of often unconscious dispositions that individuals acquire within the social forces that constrain them). While Bourdieu is also often described as a sociologist, the original insights for his later work can be found in the mainstream anthropological research that he carried out among the Kabyle peasants in Algeria (Bourdieu, 1977). Important streams of work that can be seen as developing some of the key ideas of Bourdieu include Lave and Wenger's *Situated Learning* (1991) and Levinson et al.'s *The Cultural Production of the Educated Person* (1996). Interestingly, one area of research that Bourdieu pioneered – the anthropological study of the professoriate undertaken in *Homo Academicus* (1988) – has gained much less traction. While there have been some anthropological studies of the changing environment of higher education (Bailey, 1977; Strathern, 2000) and some ethnographies of student culture (Moffatt, 1989; Nathan, 2005), detailed ethnographic studies of academics have been as Poole (2010), in one of the few exceptions to this rule, points out virtually nonexistent.

At the same time as ethnographers were examining the ways in which education systems reproduced class and ethnic inequalities, feminist anthropologists in many Western societies became interested in studying the mechanisms whereby gender patterns and inequalities were reproduced through the same system (Okely, 1978). Overall, therefore, by the end of the 1970s, the anthropology of education could be described as one of the most politically active areas of the discipline as well as one of the few areas where Western anthropologists were actively making studies of, and becoming involved in, policy making in their own societies.

From the end of the 1970s, anthropologists of education became rather more outward looking, although they often remained politically committed. In part, this involved more applied work being undertaken by anthropologists in developing countries. This work often identified closely with the ideas of the anticolonial movement and was sometimes highly critical of the manner in which Western educational systems had been 'imposed' on developing countries and tried to show how this had sometimes led to social disintegration rather than integration (Foley, 1977). Perhaps more influential for policies in the west, however, were an increasing number of detailed ethnographic studies by anthropologists of the operation of the education systems of societies whose economies seemed to be rapidly developing at a time when those of the USA and Western Europe seemed, in the late 1970s and early 1980s, to be stagnating.

A large number of works on the anthropology of Japanese education, in particular, began to appear in the light of Japan's astonishing economic growth during the 1980s, which many commentators both inside and outside Japan believed could best be explained by its education system. While some politicians in the west seemed to suggest that Japan might provide a model for the reform of their own education systems, particularly preschool and elementary systems, most anthropologists pointed out the problems inherent in the piecemeal importation of elements of a foreign education system and the impossibility of adopting a system wholesale. Instead, they urged policy makers to use descriptions of foreign education systems as a mirror for examining the strengths and weaknesses of their own systems (Rohlen, 1983).

The fourth major phase in the history of the anthropology of education involved a change of focus from studying those who run and organize education and other socialization systems to looking at the cognitive worlds of those being educated (Amit-Talai and Wulff, 1995). While there had been calls within anthropology since the 1970s, influenced largely by the work of Edwin Ardener, for children, along with women, to be given their own voice in ethnographies (Hardman, 1973), this really only began to emerge two decades later. An impetus for this development may in part have been the United Nations Convention on the Rights of the Child. The Convention certainly sparked intense debate in many countries throughout the 1990s about what constituted a 'child' and what were 'children's rights.' Ideas about the 'child' and 'childhood' were shown to differ greatly between societies with consequent implications for issues of punishment and control in the formal educational institutions in those countries; some commentators indeed felt that the Convention represented an overly Anglo-Saxon view of the child that was being ethnocentrically imposed on other societies (Boyden, 1990).

The twenty-first century has seen both a great growth and diversification of work on the anthropology of education. There is a clear tension, for example, between those who see their work in terms of advocacy and those who see it in terms of providing empirical 'scientific' accounts. This can perhaps best be seen in the mission statements of different international organizations. For example, the Council on Anthropology and Education, which is a section of the American Anthropological Association, describes its mission as 'to advance antioppressive, socially equitable, and racially just solutions to educational problems through research using anthropological perspectives, theories, methods.' On the other hand, another group, Ethnography and Education International, is 'committed to the development of ethnography in education as a vital research methodology that prioritizes the perspectives of people's lives.' Its focus is 'support ethnographic research that involves long-term engagement with those studied in order to understand their cultures, to use multiple methods of generating data, and to recognize the centrality of the researcher in the research process.' There has been a growing interest by members of this group in the ethnographic study of online communities and the effects of new technologies in teaching and learning.

Another interesting tension can be found within the Comparative and International Education Society, which is a cross-disciplinary organization that includes historians, sociologists, economists, psychologists as well as anthropologists, and educators. Its focus is on the 'theoretical basis of comparative studies (as applied to) policy and implementation issues in developing countries and cross-cultural settings.' In recent years, there has been an interesting debate within the society between anthropologists and world culture theorists; the former arguing for the need to focus on diverging local understandings of, and variations in, teaching and learning, the latter on converging global institutional forms that have developed in educational systems. Anderson-Levitt (2003) has

tried to span this divide by arguing that it is possible to have common structures but different lived experiences in educational systems around the world. As she points out, the ideas about 'teacher autonomy' or 'student participation' can have very different meanings in different contexts depending on how a society defines the idea of a 'teacher' or 'student' (and the appropriate relationship between them) at any particular point in time. The case studies in her book also show how global discourses are interpreted and consumed in local contexts and not just passively implemented. A more recently edited volume by Anderson-Levitt (2012) shows how ethnographic practices and anthropological approaches to the study of education have also developed differently in different national settings.

As will be evident, the anthropology of education these days covers all societies and all aspects of the learning and teaching process from the most formal to the most informal. The full range of topics and approaches that the contemporary anthropologist of education covers can be seen in the recently published *A Companion to the Anthropology of Education* (edited by Levinson and Pollock), which includes work by 50 of the leading scholars in the field.

Assumptions

There are two overlapping sets of assumptions that need to be examined in order to explain the (often unconscious) different approaches that anthropologists have taken to the study of education. The first set relates to whether the anthropologist's primary interest is in the way education systems structure the behavior of individuals or in the way individuals construct education systems. This dichotomy is often described as one between a focus on 'structure' or 'agency.'

The second set of assumptions relate to the ideas – held both by the researcher and the society being researched, though these may not be the same – about how the process of socialization actually operates. For example, in the case of socializing children, is the child a passive object waiting to be molded by society, or an already formed individual who just needs an environment in which he or she can naturally develop, or a person intent on pursuing his or her own interests and on whom society has to impose its will (see Jahoda and Lewis, 1988)? Sometimes, these distinctions are discussed in terms of the child as *tabula rasa*, the Apollonian child (the child as naturally good) and the Dionysian child (the child as innately willful).

Approaches that concentrate on how socialization systems, particularly formal education systems, help to construct, disseminate, and legitimate a commonly understood and accepted ritual and symbolic language and system of meaning within a society, thereby structuring the experience of individuals who are often presented as *tabula rasa*, are often described as Durkheimian or functionalist. Such analyses have been particularly influential in the study of large-scale modern societies where it is impossible for all the individuals to know each other personally. Formal education systems have played a major role in the formation of the modern nation state; they have often been the main means through which a common language has been disseminated and a national identity constructed in a population. Through their interaction with the economic and religious elements of the social system, they have helped to develop a national work ethic and inculcate national spiritual values. The study of education, therefore, has clearly been important in the work of anthropologists of ethnicity and nationalism such as Benedict Anderson and Ernest Gellner.

Marxist theories have also focused on the way in which education practices produce social beings but rather than seeing these as aids to social integration they have concentrated on how they maintain and reproduce social differences. Marxist and neo-Marxist approaches to the study of education largely replaced functionalist and Durkheimian approaches in the 1970s with studies of how class and ethnic inequalities were reproduced through the education system in the USA and UK. These studies showed how an education system can be systematically designed – by means of 'linguistic codes' or a 'hidden curricula' – to provide differential educational experiences for different class, ethnic, and gender groups in a society. While the structural effects of class reproduction could be examined quantitatively, the actual mechanisms of the 'black box' (as it came to be called) of education could be discerned only through intensive qualitative research undertaken by ethnographers.

Social action theorists have focused on how the individual actors in the educational setting help to construct or resist its formal structures. Unlike Durkheimians and Marxists, they do not see individuals in an education system as passive but as active participants in a process of 'cultural production.' Where active participation supports the integrative or the social reproductive functions of education, the analyses of social action theorists overlap with those of Durkheimians and Marxists. As Willis (1977) showed in his account of working-class youth in the UK, for example, the subcultures of resistance formed by these youths to the middle-class curriculum often only served to recreate the class structure of the wider society. Social action theorists, however, generally suggest that there is a range of reactions to the learning process in any educational setting as well as a range of teaching styles. In describing these, they often draw, implicitly at least, on Max Weber's concept of 'ideal types.' Christina Toren, who established the first European Centre specifically for the anthropological study of childhood, has focused on how the study of children's learning is an important window into how humans in general come to be who they uniquely are through interaction with others (Toren, 1999). Her work, which draws on the psychologist Piaget's idea of 'schemas' and the philosopher Merleau-Ponty's ideas of intersubjectivity, constitutes what she has called an 'anthropology of consciousness.'

Understanding the differences between the positions outlined above is important in the discipline of anthropology as anthropologists are generally themselves the main research tools. The assumptions on which anthropologists base their research affect not only what they look at but also the types of questions they ask and the conclusions they are likely to draw.

Methodology

While there are a number of antecedents to the ethnographic approach to the study of society, it was largely patented and

systematized by Malinowski in the 1920s and became closely associated with the discipline of social anthropology. The application of this approach may be the most significant contribution made by anthropology to the study of education. Almost all anthropologists of education have relied on some form of field research, ranging from total participant observation to informal interviews (Woods, 1986). Through all of these techniques, the researcher tries to gain an understanding of the participants' – teachers,' pupils,' parents,' and officials' – views on the educational process. In its ideal form, indeed, the researcher becomes through participant observation socialized in the society or institution being studied and thereby subjectively comes to empathize with and understand its values.

While field research has been shown to be a very effective means of understanding how socialization works in the broadest sense, it has perhaps particularly been suited to the study of education in 'bounded' institutions, with clearly defined boundaries in terms of time and space, such as schools, churches, and other environments where children are taught basic social categories formally and informally. When children start formal schooling in Western societies, for example, they learn how concepts of time – work time vs play time, school time vs home time, holiday time vs term time – and space – public vs private, male vs female, safe vs dangerous – are divided in the extradomestic environment. Such institutions, therefore, provide an excellent setting to investigate what are considered to be, in a particular society at a particular point in time, its core social values and how these values are socialized – through teaching the meaning of dominant symbols and key ritual performance – and legitimated through reference to ideas of 'tradition' and 'culture.' Field research also allows the researcher to gain a sense of the extent to which these values are accepted, rejected, or ignored by those being taught them.

Contribution to the Study of Education

The discipline of anthropology has brought a number of important points to bear on the study of education – a relativistic perspective of socialization practices, a holistic approach, and an ethnographic method that allows for the simultaneous study of structure and agency in the educational process – which have all become standard practice in the field even if they are not always associated directly in researchers' minds with anthropology. At the same time, the study of education has become increasingly common in anthropological accounts, generally under the headings of the study of ethnicity and nationalism, cognitive and psychological anthropology, or the growing field of the anthropology of children rather than as a distinctive field of educational anthropology.

Abstract

The explosion of research work on the economics of education has covered a wide range of issues. A key element of modern analyses is a focus on the outcomes of schooling and how various factors affect outcomes. Along with this, there has been considerable attention to production relationships and particularly to efficiency of production. The existing work suggests that variations in how well schools convert resources and inputs into student learning are a very important issue that has direct implications for education policy. Because commonly measured characteristics of teachers and schools – such as teacher experience, teacher degree levels, or class size – are not consistently related with student outcomes, the research suggests that these are not good policy instruments. On the other hand, the strong evidence about the importance of teacher quality points toward noticeable changes in the finance and governance of schools.

Study of the economics of education has expanded very rapidly, becoming one of the more popular fields of study of economists. The breadth of study is perhaps easiest to see by the fact that there are now four separate Handbook volumes addressing the various topics that are logically included in the area (Hanushek and Welch, 2006; Hanushek et al., 2011). This breadth and depth of research implies that it is logically impossible to do justice to the full field that ranges from the demand for schooling, the supply of alternative educational opportunities, and the impacts of schooling on subsequent outcomes. This discussion, rather than attempting to be exhaustive, concentrates on the more limited range of issues related to the organization, funding, and performance of schools, although these will be put into the context of the broader field.

Many facets of the broader field overlap those of labor economics, public finance, and growth theory, and they can best be put into those contexts – leaving this discussion to the unique facets of schools. The economics of education also borrows from other disciplines such as sociology and psychology, but the underlying behavior perspective remains unique to economics.

The economics of education is naturally linked to the study of human capital. Human capital refers to the skills and productive capacity embodied in individuals. While implicitly part of economics for several centuries (Kiker, 1968), the idea of human capital developed into a central concept in both theoretical and empirical analyses with the foundational work of Schultz (1961), Becker (1964), and Mincer (1970, 1974). Nonetheless, while abstractly dealing with skills and capabilities of individuals, human capital – to be both predictive and testable – must be defined in terms of more concrete measures. This requirement most often brings up school attainment as a clear, measurable aspect of human capital that can serve as a proxy for major skill differences. While an expansive view could include all research topics that touch on schooling, it is useful to define the economics of education more narrowly in terms of unique aspects not covered in other subdisciplines: namely, consideration of the education sector itself. This discussion is also limited by available data and analyses. Due to a dearth of reliable outcome data from higher education as well as schools in other countries, the economics of education has concentrated its study largely on K-12 schools. (The study of the economics of higher education, largely lacking student performance information, has directed most attention to issues of access and attendance and particularly of the influence of financial aid and costs on these (see, for example, McPherson and Schapiro (2006), Kane (2006), or Bettinger et al. (2009)). More recent analyses, benefiting from an expansion of administrative data for higher education, have moved to other questions about the production process (for example, Bound and Turner (2007) or Bettinger and Long (2010)). Nonetheless, because these analyses have such a different perspective from those related to primary and secondary education, they are not included in this discussion.)

Interestingly, however, the field has rapidly expanded to cover the entire world. While once restricted largely to American schools, data and analysis have expanded to cover the globe.
